PROTOCOL SYNOPSIS

PROTOCOL NO.: 2019nCoV-302

TITLE: A Phase 3, Randomised, Observer-Blinded, Placebo-Controlled Trial to Evaluate the Efficacy and Safety of a SARS-CoV-2 Recombinant Spike Protein Nanoparticle Vaccine (SARS-CoV-2 rS) with Matrix-M1™ Adjuvant in Adult Participants 18-84 Years of Age in the United Kingdom

STUDY PHASE: Phase 3

STUDY SITES: 28 sites across the United Kingdom (UK).

OBJECTIVES:

- **The primary objective is:**
 - To demonstrate the efficacy of SARS-CoV-2 rS with Matrix-M1 adjuvant in the prevention of virologically confirmed (by polymerase chain reaction [PCR] to severe acute respiratory syndrome coronavirus 2 [SARS-CoV-2]), symptomatic coronavirus disease 2019 (COVID-19), when given as a 2-dose vaccination regimen, as compared to placebo, in serologically negative (to SARS-CoV-2) adults.
- **The secondary objectives are:**
 - To demonstrate the efficacy of SARS-CoV-2 rS with Matrix-M1 adjuvant in the prevention of virologically confirmed (by PCR to SARS-CoV-2), symptomatic COVID-19, when given as a 2-dose vaccination regimen, as compared to placebo, in adults regardless of their serostatus at baseline.
 - To assess the efficacy of SARS-CoV-2 rS with Matrix-M1 adjuvant on SARS-CoV-2 seropositive adult participants requiring specific medical interventions as compared to placebo.
 - To assess the efficacy of SARS-CoV-2 rS with Matrix-M1 adjuvant on mild COVID-19 symptoms as compared to placebo.
 - To assess the efficacy of SARS-CoV-2 rS with Matrix-M1 adjuvant on occurrence of asymptomatic or undetected infections with SARS-CoV-2 as compared to placebo.
 - In a subset of adult participants, to evaluate the immunogenicity of SARS-CoV-2 rS with Matrix-M1 adjuvant as compared to placebo.
 - To evaluate safety in terms of serious adverse events (SAEs) and medically attended adverse events (MAAEs) related to study vaccination in all adult participants during the entire study period.
 - To evaluate safety in terms of adverse events of special interest (AESIs), which encompasses potential immune-mediated medical conditions (PIMMCs) and

AESIs relevant to COVID-19 including possible vaccine-enhanced disease, in all adult participants at any time after the first dose.

- In a subset of adult participants, to evaluate the safety and reactogenicity in terms of solicited local and systemic adverse events (AEs) for 7 days after each study vaccination.
- To evaluate safety in terms of all MAAEs for 14 days after second vaccination and unsolicited AEs for 21 days after first study vaccination and 28 days after second study vaccination.
- **The exploratory objectives are:**
 - In a subset of adult participants, to evaluate the safety and immunogenicity of SARS-CoV-2 rS with Matrix-M1 adjuvant when co-administered with a licensed seasonal influenza vaccine.

ENDPOINTS

- **The primary endpoint is:**
 - First occurrence of virologically confirmed (by PCR to SARS-CoV-2), symptomatic mild, moderate, or severe COVID-19 with onset at least 7 days after second study vaccination (e.g., Day 28) in serologically negative (to SARS-CoV-2) adult participants at baseline until the endpoint-driven efficacy analysis is triggered by the occurrence of a prespecified number of blinded endpoints.
- **The key secondary endpoint is:**
 - First occurrence of virologically confirmed (by PCR to SARS-CoV-2), symptomatic moderate or severe COVID-19 with onset at least 7 days after second study vaccination (e.g., Day 28) in serologically negative (to SARS-CoV-2) adult participants at baseline until the endpoint-driven efficacy analysis is triggered by the occurrence of a prespecified number of blinded endpoints.
- **The other secondary endpoints are:**
 - First occurrence of virologically confirmed (by PCR to SARS-CoV-2), symptomatic mild, moderate, or severe COVID-19, with onset at least 7 days after second study vaccination (e.g., Day 28) in adult participants regardless of their serostatus at baseline.
 - First occurrence of COVID-19 requiring hospitalisation, intensive care unit (ICU) admission or mechanical ventilation linked to any virologically confirmed (by PCR to SARS-CoV-2) COVID-19 with onset at least 7 days after second study vaccination (e.g., Day 28) in adult participants regardless of their serostatus at baseline.
 - First occurrence of virologically confirmed (by PCR to SARS-CoV-2), symptomatic mild COVID-19 (with no progression to moderate or severe COVID-19 during the course of the COVID-19 episode) with onset at least 7 days after second study vaccination (e.g., Day 28) in adult participants, regardless of their serostatus at baseline.

- First occurrence of laboratory-confirmed (by PCR or nucleocapsid [N]-protein serology to SARS-CoV-2) symptomatic or asymptomatic COVID-19 with onset at least 7 days after second study vaccination (e.g., Day 28) in adult participants regardless of their serostatus at baseline.
- Analysis of antibodies binding to the SARS-CoV-2 spike (S) protein by enzyme-linked immunosorbent assay (ELISA) at Day 0 (baseline) and Day 35 (14 days after second study vaccination).
- The occurrence and relationship to study vaccination of SAEs and MAAEs related to study vaccination (in all adult participants) during the entire study period.
- The occurrence and relationship to study vaccination of AESIs and PIMMCs (in all adult participants) during the entire study period.
- The occurrence and severity of reactogenicity in terms of solicited local and systemic AEs (in sub-study participants) for 7 days after each study vaccination.
- The occurrence, severity, and relationship to study vaccination of all MAAEs for 14 days after second vaccination and unsolicited AEs (in all adult participants) for 21 days after first study vaccination and 28 days after second study vaccination.
- **Exploratory endpoints are:**
 - First occurrence of virologically confirmed (by PCR to SARS-CoV-2), symptomatic mild, moderate, or severe COVID-19 with onset at least 14 days after first study vaccination (e.g., Day 14) in serologically negative (to SARS-CoV-2) adult participants at baseline until the endpoint-driven efficacy analysis is triggered by the occurrence of a prespecified number of blinded endpoints.
 - Any occurrence of serologic conversion (by serology to SARS-CoV-2 N protein) between baseline and 1 year after last study vaccination in adult participants seronegative at baseline.
 - Analysis of the proportion of adult participants with evidence of seroconversion as demonstrated by binding antibodies to the SARS-CoV-2 S protein by ELISA at Day 35 (14 days after second study vaccination).
 - Analysis of the cell-mediated immune responses (for example, as measured by enzyme-linked immune absorbent spot (ELISpot) ± intracellular cytokine staining) on Days 0 (baseline) and 35 (14 days after second study vaccination).
 - SARS-CoV-2 neutralisation as measured by virus neutralisation assay (VNA; wild-type virus and/or pseudovirion expressing SARS-CoV-2 S protein) at Day 0 (baseline) and Day 35 (14 days after second study vaccination).
 - Analysis of the safety and immunogenicity of SARS-CoV-2 rS with Matrix-M1 adjuvant when co-administered with seasonal influenza vaccine in a subset population.

STUDY DESIGN:

This is a Phase 3, multi-centre, randomised, observer-blind, placebo-controlled study evaluating the efficacy, safety, and immunogenicity of SARS-CoV-2 rS with Matrix-M1 adjuvant in adult participants 18 to 84 years of age (inclusive) in the UK. Every effort will be made to identify sites of high SARS-CoV-2 activity, and populations within these sites who are at high risk of exposure to the virus will be enrolled such that the incidence of COVID-19 in the study will be higher than 1% and the sample size and enrolment period may be reduced.

After signing informed consent, participants may be screened within a window of up to approximately 30 days. During the screening period, nose/throat samples may be taken to detect SARS-CoV-2 by PCR, if the participant has any COVID-19 symptoms or significant exposure history.

Approximately 15,000 male and female adult participants 18 to 84 years of age (inclusive) with and without relevant comorbidities are planned for the study. An effort will be made to enrol a target of at least 25% of participants who are ≥ 65 years of age as well as prioritising other groups that are most affected by COVID-19, including racial and ethnic minorities. This will be under the assumption that the annual incidence of symptomatic COVID-19 will be approximately 1% to 5%.

The sample size may be adjusted by the sponsor during the study, based on blinded data, to ensure sufficient power at the time of the primary analysis. Details on the possible sample-size reassessment will be described in the statistical analysis plan (SAP).

On Day 0, nose/throat samples will be taken to detect PCR for SARS-CoV-2 and blood samples will be taken to detect any existing SARS-CoV-2 antibodies at baseline. Participants will be randomised in a 1:1 ratio via block randomisation to receive 2 intramuscular (IM) injections of the SARS-CoV-2 rS with Matrix-M1 adjuvant or placebo, as described in [Table S1-1](#).

Table S1-1 Study Vaccine Groups

Study Vaccine Groups	Number of Randomised Participants	2 Vaccinations	
		Day 0	Day 21 (+ 7 days)
SARS-CoV-2 rS (5 µg) + Matrix-M1 adjuvant (50 µg)	N = 7,500	X	X
Placebo	N = 7,500	X	X

Randomisation will be stratified by site and by age ≥ 65 years. In addition, there will not be specific age sub-stratification recruitment targets within the ≥ 65 -year age group, but through site recruitment; the aim is to allow a generally representative age distribution overall.

The study will consist of the screening period (Days -30 to 0); study vaccination days (Days 0 and 21 (+7-day window)); and outpatient study visits on Day 0, Day 21 (+ 7 days), and Day 35 (14 days minimum after second study vaccination [+ 7 days]); and at 3, 6, and 12 months (± 15 days) after last study vaccination.

The duration of individual participation, including screening, will be a maximum of 1 year after last study vaccination (Day 386 ± 15 days). This will be an event-driven study for the assessment of vaccine efficacy (VE) and will end when a sufficient number of events have

been observed, yet all participants will be followed for the entire study duration for safety endpoints.

A licensed seasonal influenza co-administration sub-study will be conducted in the first 400 participants who meet the additional inclusion criteria for this study. Participants may be enrolled at selected study sites due to the availability of seasonal influenza vaccine. After being randomised to receive intramuscular (IM) injections of SARS-CoV-2 rS with Matrix-M1 adjuvant or placebo, sub-study participants will receive a licensed seasonal influenza vaccine on Day 0 in the opposite deltoid. These participants will be part of the solicited AE safety subset analysis.

Given that this study and others will enrol during the influenza virus season and that the highest at-risk population, namely the elderly and adults with comorbid conditions for influenza mirrors that of SARS-CoV-2, a co-vaccination sub-study is included. This sub-group will undergo the same safety and efficacy evaluations as the entire study population. In addition, the entire sub-study will have reactogenicity assessed. This group must not have had a current season licensed influenza vaccine and have no prior history of allergy or severe reaction to seasonal influenza vaccine. To assess the possible impact of the study vaccine on the immunogenicity of the influenza vaccine, this group will also have a hemagglutination inhibition assay (HAI) performed.

A global Safety Monitoring Committee (SMC) was convened to oversee the safety of the ongoing Phase 1/2 study (Protocol 2019nCoV-101) and will oversee one or more additional studies across the SARS-CoV-2 rS vaccine program. A separate SMC will be convened for this study. The designated SMC will monitor the safety of participants in the study and will follow an SMC charter. The SMC will review blinded and unblinded safety and reactogenicity data. The SMC will also review sufficient clinical event data to ensure detection of any evidence of enhanced disease. The SMC will convene to perform safety reviews on a scheduled basis, for immediate concerns regarding safety observations during this study, and as needed.

Study Vaccination Pause Rules:

Study vaccination pause rules based on reactogenicity, AEs, and SAEs related to study participation will be in place to monitor participant safety during the study.

AEs meeting any one of the following criteria will result in a hold being placed on subsequent study vaccinations pending further review by the SMC at the direction of the SMC chair:

- Any toxicity grade 3 or higher (severe or potentially life-threatening) solicited (local or systemic) single AE term occurring in $\geq 10\%$ of participants (after a minimum of 100 subjects are enrolled) in the SARS-CoV-2 rS with Matrix-M1 adjuvant group within the first 7 days after study vaccination.
- Any severe unsolicited single AE preferred term for which the investigator assesses as related that occurs in $\geq 5\%$ of participants (after a minimum of 100 subjects are enrolled) in the SARS-CoV-2 rS with Matrix-M1 adjuvant group, within the first 7 days after study vaccination.

In addition, any SAE assessed as related to vaccine (final assessment by the sponsor) will be reported by the sponsor to the SMC Chair as soon as possible, and within 24 hours of the sponsor's awareness of the event. Based on this initial report of the event to the SMC Chair, the Chair may advise the sponsor to immediately pause enrolment and further dosing in either some or all subjects in the study and to convene an ad hoc meeting, or make alternative recommendations. The SMC Charter defines processes for how this review will occur and how the Chair's recommendations will be documented.

The sponsor, along with medical monitor, may request an SMC review for any safety concerns that may arise in the study, even if they are not associated with any specific pause rule; for example, any SAE for which causality is at least possibly related.

The 400 subject influenza vaccine co-administration study will utilize the same pause rules with one difference due to the expectation of greater reactogenicity and the small size:

- Any grade 3 or higher (severe or potentially life-threatening) solicited (local or systemic) single AE term occurring in $\geq 20\%$ of participants in the SARS-CoV-2 rS with Matrix-M1 adjuvant plus seasonal influenza vaccine group, within the first 7 days after study vaccination.

STUDY POPULATION:

Inclusion Criteria:

Each participant must meet all of the following criteria to be enrolled in this study:

1. Adult males or females aged 18 to 84 years (inclusive) at screening.
2. Able and willing (in the investigator's opinion) to comply with all study requirements.
3. Willing to allow the investigators to discuss the volunteer's medical history with their General Practitioner and access all medical records when relevant to study procedures.
4. Willing and able to give informed consent prior to study enrolment.
5. Female participants of childbearing potential (defined as any female who has experienced menarche and who is NOT surgically sterile [i.e., hysterectomy, bilateral tubal ligation, or bilateral oophorectomy] or postmenopausal [defined as amenorrhea at least 12 consecutive months or > 1 documented plasma follicle-stimulating hormone level ≥ 40 mIU/mL]) must agree to be heterosexually inactive from at least 28 days prior to enrolment and through 3 months after the last study vaccination OR agree to consistently use any of the following methods of contraception from at least 28 days prior to enrolment and through 3 months after the last study vaccination:
 - a. Condoms (male or female)
 - b. Diaphragm with spermicide
 - c. Cervical cap with spermicide
 - d. Intrauterine device
 - e. Oral or patch contraceptives

- f. Norplant[®], Depo-Provera[®], or other in country regulatory-approved contraceptive method that is designed to protect against pregnancy
 - g. Abstinence, as a form of contraception, is acceptable if in line with the participant's lifestyle (other approaches to abstinence are not acceptable)
- NOTE:** Periodic abstinence (e.g., calendar, ovulation, symptothermal, post-ovulation methods) and withdrawal are not acceptable methods of contraception.
6. Room air oxygen saturation > 95% at Screening/Day 0.

Seasonal Influenza Vaccine Co-Administration Sub-Study Only

7. Participant should not have received a current season influenza vaccine, have no contraindication to the specific vaccine to be administered in the study, and no prior history of allergy or severe reaction to seasonal influenza vaccines.

Exclusion Criteria:

Participants meeting any of the following criteria will be excluded from the study:

1. Participation in COVID-19 prophylactic drug trials for the duration of the study.
2. Future participation in SARS-CoV-2 serological surveys where participants are informed of their serostatus for the duration of the study.
3. Participation in research involving an investigational product (drug/biologic/device) within 45 days prior to first study vaccination.
4. History of laboratory-confirmed (by PCR or serology to SARS-CoV-2) COVID-19 infection at any time prior to randomisation.
5. Administration of immunoglobulins and/or any blood products within the 3 months preceding the planned administration of the study vaccine candidate.
6. Any confirmed or suspected immunosuppressive or immunodeficient state; chronic administration (defined as more than 14 continuous days) of immunosuppressant medication within the past 3 months, except topical steroids or short-term oral steroids (course lasting \leq 14 days).

- NOTE:** An immunosuppressant dose of glucocorticoid is defined as a systemic dose \geq 10 mg of prednisone per day or equivalent. The use of topical, inhaled, and nasal glucocorticoids will be permitted if other chronic disease conditions are not exclusionary. Human immunodeficiency syndrome (HIV)-positive participants receiving highly active antiretroviral therapy and a history within 6 months of screening of viral load < 1000 copies/mL or CD4 count > 300 cells/mm³ would be eligible.
7. History of allergic disease or reactions likely to be exacerbated by any component of the study vaccines.
 8. Any history of anaphylaxis to any prior vaccine.
 9. Pregnancy, lactation, or willingness/intention to become pregnant within 3 months following the last study vaccination
 10. Current diagnosis of or treatment for cancer (except basal cell carcinoma of the skin and cervical carcinoma in situ, at the discretion of the investigator).

11. Bleeding disorder (e.g., factor deficiency, coagulopathy or platelet disorder), or prior history of significant bleeding or bruising following IM injections or venepuncture.
12. Continuous use of anticoagulants, such as coumarins and related anticoagulants (i.e., warfarin) or novel oral anticoagulants/anti-platelet agents.
NOTE: The use of ≤ 325 mg of aspirin per day as prophylaxis is permitted.
13. Suspected or known current alcohol or drug dependency.
14. Study team member or first-degree relative of any study team member (inclusive of sponsor, contract research organisation (CRO), and site personnel involved in the study).
15. Participants who are having any current workup of undiagnosed illness within the last 8 weeks that is either participant-reported or has been clinician-assessed, which could lead to a new condition or diagnosis.
16. Received any live vaccine within 4 weeks or **any vaccine** (excluding influenza) within 2 weeks prior to first study vaccination or any licensed influenza vaccine within 1 week prior to first study vaccination or plans to receive any vaccine from these time periods until 28 days after second study vaccination.
NOTE: An influenza co-administration sub-study will occur in which 400 participants will receive a single dose of seasonal influenza vaccine at the same time as first study vaccination. In addition, a licensed seasonal influenza vaccine may be given 7 days after each vaccination but should not be given within 7 days prior to second vaccination.
17. Have clinically significant chronic cardiovascular, endocrine, gastrointestinal, hepatic (including hepatitis B and C), renal, neurological, respiratory, psychiatric or other medical disorders not excluded by other exclusion criteria, that are assessed by the investigator as being clinically unstable within the prior 4 weeks as evidenced by:
 - a. Hospitalisation for the condition, including day surgical interventions.
 - b. New significant organ function deterioration.
 - c. Needing addition of new treatments or major dose adjustments of current treatments (mild or moderate well-controlled comorbidities are allowed).
18. History of chronic neurological disorders that have required prior specialist physician review for diagnosis and management (such as multiple sclerosis, dementia, transient ischemic attacks, Parkinson's disease, degenerative neurological conditions, and neuropathy) or a history of stroke or previous neurological disorder within 12 months with residual symptoms. Participants with a history of migraine or chronic headaches or nerve root compression that have been stable on treatment for the last 4 weeks are not excluded.
19. Any autoimmune disease/condition (iatrogenic or congenital) listed in [Table 9-3](#) or being treated with a biologic therapy.
NOTE: The Skin and Metabolic Disorders listed in [Table 9-3](#) are eligible at the discretion of the investigator.
20. Any other significant disease, disorder or finding that, in the opinion of the investigator, may significantly increase the risk to the volunteer because of

participation in the study, affect the ability of the volunteer to participate in the study, or impair interpretation of the study data.

21. Participant requires the use of continuous oxygen therapy or any oxygen therapy while awake or is anticipated to require daytime oxygen therapy during the course of the study.

NOTE: Nocturnal oxygen use only is acceptable for study inclusion.

Other Considerations:

Participants meeting any of the following criteria may have planned study vaccination deferred for a later date, but these criteria are not exclusionary for study enrolment.

- Respiratory symptoms in the past 3 days (i.e., cough, sore throat, difficulty breathing). Participant may be vaccinated once all symptoms have been resolved for > 3 days. Out-of-window study vaccination is allowed for this reason (see NOTE).
- Temperature of > 38°C within 24 hours of planned study vaccination (site measured or participant measured). Participant may be vaccinated once the fever has resolved and there has not been any temperature measured as being > 38°C for > 3 days. Out-of-window study vaccination is allowed for this reason (see NOTE).

NOTE: PCR testing for SARS-CoV-2 is likely to be indicated for either of the above reasons or if COVID-19 is suspected based on other symptoms, potential exposure to SARS-CoV-2 infection through either close contacts or based on local epidemiology. If a participant has a positive PCR for SARS-CoV-2 prior to enrolment that participant will not be eligible and will be considered a screen failure.

- Participants having any symptoms or signs of possible COVID-19 infection (Table 2-2) that may also be due to post-vaccination reactogenicity within 7 days of either study vaccine dose will NOT be required to be tested for SARS-CoV-2 PCR.
- Any participant with a new positive PCR-confirmed SARS-CoV-2 infection occurring from Screening and prior to second study vaccination will not be removed from the study but must meet health requirements before receiving second study vaccination.
- Any participant who has a positive PCR for SARS-CoV-2 between the first and second study vaccination should also have PCR testing for SARS-CoV-2 on the day of the subsequent study vaccination, but the results of the PCR test are not needed before study vaccination can be given.
- Any participant with a new positive PCR-confirmed SARS-CoV-2 infection occurring from Screening and prior to the end of immunogenicity assessments will be removed from applicable immunogenicity analyses as defined in the SAP.
- Any acute illness (cardiovascular, endocrine, gastrointestinal, hepatic, renal, neurological, respiratory, or other medical disorders) that is actively causing symptoms that could, in the opinion of the investigator, impact the assessment of reactogenicity or other study assessments may have planned study vaccination deferred for a later date, but these criteria are not exclusionary for study

enrolment. Participant may be vaccinated once symptoms have resolved or are stabilised for > 3 days. Out-of-window study vaccination is allowed for this reason.

- Any participant who is otherwise eligible with a blood pressure of $\geq 160/100$ mmHg may be retested onsite several times over a 3-hour interval to achieve a lower blood pressure. If the blood pressure remains $\geq 160/100$ mmHg, study vaccination should be deferred for a later date if the baseline blood pressure is found to be $< 160/100$ mmHg.

STUDY VACCINES:

Study vaccinations (5- μ g SARS-CoV-2 rS with 50- μ g Matrix-M1 adjuvant or placebo [saline]) will comprise 2 IM injections on Days 0 and 21, ideally in alternating deltoids. For blinding purposes, all participants will be vaccinated using the same injection volume (i.e., 0.5 mL).

The seasonal influenza vaccine co-administration sub-study will comprise a single IM injection (0.5 mL) of a licensed influenza vaccine on Day 0, ideally in the opposite deltoid of the study vaccine. Flucelvax Quadrivalent will be given to those 18 to 64 years of age, and an adjuvanted trivalent influenza vaccine will be given to those ≥ 65 years of age.

Whenever possible the RIGHT deltoid will be used for the influenza vaccine and the LEFT deltoid for the study vaccine.

All study vaccinations will be administered on an outpatient basis by designated site personnel in a way to maintain the blind. The influenza vaccine will not require blinding. Any pharmacy preparation with unblinded product will require unblinded site personnel who will not otherwise be involved in the study procedures or observation of participants.

STUDY PROCEDURES:

Study procedures, including efficacy, immunogenicity, and safety assessments are listed in the schedule of events (SOE) in [Table 3-1](#).

Efficacy Assessments:

Nose/Throat Testing for SARS-CoV-2 Detection and Confirmation:

Nose/throat samples for virus detection will be taken at the study visits described in the SOE ([Table 3-1](#)).

Nose/throat sampling will be performed to virologically confirm (by PCR to SARS-CoV-2) the presence of SARS-CoV-2 beginning on Day 0 until the end of study (EOS), yet only those SARS-CoV-2 cases detected 7 days after second study vaccination will be utilised in study efficacy endpoints.

Monitoring for COVID-19:

Identification and laboratory confirmation of SARS-CoV-2 infection and symptomatic COVID-19 will be performed throughout the study.

On study enrolment, participants will be given details of a 24/7 on-call number to contact the study team. Participants will be instructed to contact the study team within 24 hours via this

number if they self-assess COVID-19 symptoms in [Table 2-2](#) or are clinically concerned. Newly discovered symptoms of suspected COVID-19 will trigger a COVID-19 Surveillance Visit. Please refer to [Table 2-2](#) for the qualifying symptoms of suspected COVID-19 disease. Participants will receive weekly reminders (email or text messages) to immediately contact the study team if they have experienced any new symptoms or health concerns that could be related to infection with SARS-CoV-2. Newly discovered symptoms of suspected COVID-19 will trigger a COVID-19 Surveillance Visit. A participant with suspected or confirmed COVID-19 will be asked to complete the COVID-19 symptom diary. Participants should start the diary on their first day of symptoms and complete this diary daily for a minimum of 10 days even if their symptoms have resolved and regardless of any SARS-CoV-2 PCR results. They should continue the diary beyond 10 days if they have any ongoing symptoms related to the episode and should continue to do so until all symptoms have resolved.

The occurrence of COVID-19-related hospitalisation and COVID-19-related complications (such as, but not limited to, pneumonia, neurological or vascular complications, severe pneumonia, severe neurological or vascular events, acute respiratory distress syndrome, renal complications, sepsis, septic shock, death) will be monitored throughout the study. Every episode of a new onset of symptoms of suspected COVID-19 will trigger a COVID-19 Surveillance Visit (Initial and Follow-Up). A “new onset” episode will require at least a 7-day period of being symptom-free prior to the event to differentiate a specific episode from any prior illness.

Immunogenicity Assessments:

Blood will be collected from all participants for humoral immunogenicity according to the time points specified in the SOE ([Table 3-1](#)).

Immune measurements (ELISA) will be conducted on serum (immunoglobulin G [IgG]) for SARS-CoV-2 anti-S protein serology in approximately 900 participants in the Anti-S Protein Serology Subset and on anti-N protein serology in all participants. The immunologic test for SARS-CoV-2 serology based on a non-S protein (e.g., SARS-CoV-2 N protein) will be performed to identify cases of asymptomatic infection. Additional immunogenicity assessments specific to SARS-CoV-2 (or related variants) will include a neutralising antibody assay, which will be performed in approximately 900 participants in a Neutralisation Assay Subset. Cell-mediated immune responses, as assessed by ELISpot ± intracellular cytokine staining, will be performed in approximately 450 participants in the Cell-mediated Assay Subset. In addition, an HAI will be performed in the approximately 400 participants in the seasonal influenza vaccine co-administration sub-study.

Safety Assessments:

The timing and frequency of all safety assessments are listed in the SOE ([Table 3-1](#)).

After each study vaccination, including the licensed seasonal influenza vaccine for participants in the seasonal influenza vaccine co-administration sub-study, participants will remain under observation at the study site for at least 30 minutes for the presence of any acute reactions and solicited AEs. Solicited AEs, collected through an electronic diary (e-Diary), will be recorded from the time of study vaccination until 7 days after study vaccination in all participants in the seasonal influenza vaccine co-administration sub-study and a subgroup of all other participants. Participants in the licensed seasonal influenza

vaccine co-administration sub-study will record local reactogenicity for the study vaccine injection site only.

All participants will be assessed for unsolicited AEs from the time of first study vaccination until Day 49; SAEs will be assessed from the time the informed consent is signed until completion of the participant's last study-related procedure; all MAAEs will be reported from the time of first study vaccination until Day 35; MAAEs related to study vaccination and AESIs will be reported from the time of first study vaccination until completion of the participant's last study-related procedure. All AEs will be followed until resolution or until clinically stable.

Safety assessments will include monitoring and recording of solicited (local and systemic reactogenicity events) and unsolicited AEs; MAAEs; AESI; SAEs; vital sign measurements on day of study vaccinations; and physical examination findings. COVID-19 severity will be categorised as virologically confirmed, mild, moderate, or severe according to protocol-specified criteria (Table 2-1). Recording of solicited and unsolicited AEs may be conducted by electronic data capture (EDC)/reporting. Potential immune-mediated medical conditions (PIMMC) and AESIs specific to potential disease enhancement for COVID-19 will also be monitored (see Section 9.5 [Appendix 4] for details).

STATISTICAL ANALYSIS PLANS:

Sample Size:

This study is designed to enrol approximately 15,000 participants, randomised 1:1 into the 2 study vaccine groups. The sample size is driven by the total number of events expected to achieve statistical significance for the primary efficacy endpoint – a target of 152 mild, moderate, or severe COVID-19 cases. The target number of events of 152 was chosen to provide 90% overall power for 60% vaccine efficacy (VE). Two formal interim analyses of efficacy and futility will be conducted based on the accumulation of approximately 43% (66 events) and 72% (110 events) of the total anticipated primary endpoints using O'Brien-Fleming boundary conditions. Power calculations were performed using 10,000 simulated trials that were created under various assumptions of VEs and analysed using methods described in the "efficacy analysis" section without covariates. A 90% evaluability rate for the per-protocol (PP) efficacy (PP-EFF) population (assuming 10% unevaluable due to attrition and/or baseline-seropositive participants) was used for the power calculations. All simulations were performed in SAS V9.4.

Analysis Sets:

The all-randomised set will include all participants who were randomised regardless of the receipt of any study vaccine (SARS-CoV-2 rS with Matrix-M1 adjuvant or placebo). The all-randomised set will be used for the subject disposition summaries.

The intent-to-treat (ITT) analysis set will include all participants who are randomised and receive at least 1 dose study vaccine (SARS-CoV-2 rS with Matrix-M1 adjuvant or placebo), regardless of protocol violations or missing data. The ITT analysis set will be used as a supportive analysis population for the immunogenicity and efficacy analyses and will be analysed according to the study vaccine group as randomised.

The safety analysis set will include all participants who receive at least 1 dose of study vaccine (SARS-CoV-2 rS with Matrix-M1 adjuvant or placebo). Participants in the safety analysis set will be analysed according to the study vaccine actually received.

The PP-EFF will include baseline seronegative participants who receive both doses of study vaccine (SARS-CoV-2 rS with Matrix-M1 adjuvant or placebo) and have no major protocol deviations that occur before the first COVID-19 episode affecting the primary efficacy outcome as assessed by the sponsor prior to unblinding. All analyses of the PP-EFF population will also exclude any illness episodes with positive SARS-CoV-2 by any validated PCR or antibody test occurring before 7 days after second study vaccination (e.g., Day 28).

The per-protocol immunogenicity (PP-IMM) analysis set for each post-randomisation visit will include participants who receive scheduled dose(s) of study vaccine (SARS-CoV-2 rS with Matrix-M1 adjuvant or placebo), have at least a baseline and the serum sample result for the visit available after study vaccination, and have no major protocol violations that are considered clinically likely to impact the immunogenicity response at the corresponding study visit as assessed by the sponsor prior to unblinding. For each visit, the SARS-CoV-2 unexposed population will also exclude any illness episodes with positive SARS-CoV-2 by any validated PCR or antibody test prior to each visit. Prior exposed participants will be determined using baseline SARS-CoV-2 immunity defined as positive SARS-CoV-2 by PCR or serum IgG antibody at baseline, or positive SARS-CoV-2 by qualitative PCR through Day 35, according to the specified analysis. Analysis will be performed to assess if immune responses differ between exposed and unexposed individuals (i.e., whether prior exposure alters dosing regimen considerations in a pandemic response).

The review and determination for exclusion from the PP populations will be carried out in a blinded fashion by a study clinician prior to unblinding for each interim analysis based on all available information from the locked database. Both PP populations will be analysed according to the study vaccine group as randomised.

Efficacy Analyses:

The primary endpoint will be analysed on the PP-EFF Analysis Set and supported by analysis of the ITT Analysis Set. Conclusions concerning declaration of attainment of the primary endpoint at the completion of the study will only be based on the PP-EFF population.

VE is defined as $VE (\%) = (1 - RR) \times 100$, where RR = relative risk of incidence rates between the 2 study vaccine groups (SARS-CoV-2 rS with Matrix-M1 adjuvant or placebo). The final analysis for the primary objective in the PP-EFF population will be carried out at the overall one-sided Type I error rate of 0.025 for the 3 planned analyses. The nominal alpha to be spent for the final analysis will be recalculated using the Lan-DeMets alpha spending function based on the actual numbers of events used for the interim analyses and the numbers of endpoints to be used for the final analysis. The estimated RR and its CI will be derived using Poisson regression with robust error variance [Zou 2004]. The explanatory variables in the model will include study vaccine group. The dependent variable will be the incidence rate of the endpoint of interest. The robust error variances will be estimated using the repeated statement and the participant identifier. The Poisson distribution will be used with a

logarithm link function. The site (depending on the distribution of endpoints) and the age strata will be included in the model as covariates. To assess incidence rates rather than absolute counts of cases, accounting for differences in follow-up times starting with 7 days after the second vaccination among participants, an offset will be utilized in the Poisson regression. In case the total number of events to be analysed may be too low for an asymptotic method proposed (i.e., ≤ 5 events in either treatment group), an alternative method based on the single sample exact binomial distribution may be used for the analysis. This method is based on the proportion of the events in the SARS-CoV-2 rS with Matrix-M1 adjuvant group among the total number of events observed in both treatment groups after adjusting for the differential number of subjects (or inclusive of differential lengths of follow-up) between the 2 treatment groups.

Hypothesis testing of the primary efficacy endpoint will be carried out against $H_0: VE \leq 30\%$. Rejection of the null hypothesis, $H_0: VE \leq 30\%$ demonstrates a statistically significant vaccine effect (i.e., alpha-adjusted lower bound confidence interval [LBCI] $> 30\%$) will be considered meeting the pre-specified study success criterion. The study will also continue for the intended duration to measure efficacy, immunogenicity, and safety endpoints, regardless of primary endpoint success at the interim analyses or the final efficacy analysis. The final formal analysis of the primary efficacy endpoint will be triggered when approximately 152 PP-EFF participants with symptomatic mild, moderate, or severe COVID-19 endpoints have accrued. Also, in order to be able to respond to the unexpected and rapidly evolving COVID-19 pandemic situation globally, other factors such as requests by government or public health agencies may also be factored into the decision-making to unblind the study for the final analysis, but this always occurs in consultation with lead regulatory agencies.

The secondary and exploratory efficacy endpoints will be analysed using the same method as the primary efficacy analysis described above. Analysis of secondary and exploratory efficacy endpoints will be performed without adjustment for multiple comparisons (i.e., two-sided alpha of 0.05). The final interpretation of the overall vaccine efficacy will be based on the totality of statistical evidence, including immunogenicity results and the clinical importance in discussions with the regulatory agencies and scientific communities.

The EOS analysis will be performed when the last participant completes the last visit (12 months after the last study vaccination) or discontinues earlier.

Immunogenicity Analyses:

The primary and secondary immunogenicity analyses will be performed using the PP-IMM and ITT analysis populations.

For the serum antibody levels measured by microneutralization and HAI assays, the geometric mean at each study visit, the geometric mean fold rises (GMFRs) comparing to Day 0 (baseline) at each follow-up study visit, along with 95% CI will be summarised by study vaccine group. The 95% CI will be calculated based on the t distribution of the log-transformed values for geometric means or GMFRs, then back transformed to the original scale for presentation. The seroconversion rate (SCR), proportion of participants with ≥ 4 fold rises if naïve at baseline, along with 95% CIs based on the Clopper-Pearson method will be summarised by study vaccine group at each follow-up study visit.

For the subset of participants who receives the influenza vaccine concurrently with the study vaccines, comparisons of strain-specific immune responses to influenza vaccine as measured by HAI will be performed. The treatment comparison will be made by comparing the strain-specific geometric mean titres (GMTs) and the SCRs. The SCR is defined as the proportion of subjects with either a baseline reciprocal (Day 0) titre of < 10 and a post-vaccination reciprocal titre ≥ 40 , or a baseline titre of ≥ 10 and a post-vaccination titre ≥ 4 -fold higher.

For strain-specific GMTs in each treatment group, titres reported below the lower limit of quantitation (LLOQ; i.e., below the starting dilution of assay reported as “ < 10 ”) will be set to half that limit (i.e., $10 / 2 = 5$). Strain-specific GMTs will be summarized by treatment group and visit day along with the corresponding two-sided 95% CIs, by exponentiating the corresponding log-transformed means and their 95% CIs. The ratio of GMTs between treatment groups post-vaccination and the corresponding two-sided 95% CI will be calculated on log-transformed titres using the analysis of covariance (ANCOVA) with treatment group and baseline (Day 0) measurement as the covariate.

For strain-specific SCRs, the rate in percent and the corresponding two-sided exact binomial 95% CIs will be calculated using the Clopper-Pearson method. The two-sided 95% CIs for the absolute rate difference between the 2 treatment groups will be constructed using the Newcombe method.

Similar summaries will be generated for the other immunogenicity endpoints and other assays if conducted.

Correlates of risk will be assessed where immune responses are measured in all available participants, and the results compared between participants who experience a SARS-CoV-2 event and participants who do not. The goal of this analysis is to assess correlates of risk of SARS-CoV-2 infection (and potential other secondary endpoints) in the study vaccine group by comparing study vaccine-induced immune responses associated with COVID-19.

The EOS analysis will be performed when all participants in the Neutralisation Assay Subset have completed the last study visit or discontinued earlier.

Safety Analyses:

Solicited AEs (e.g., local and general systemic reactogenicity symptoms) will be captured in the Safety Subset of approximately 2,000 participants and in the seasonal influenza vaccine co-administration sub-study of approximately 400 participants.

Numbers and percentages (with 95% CIs based on the Clopper-Pearson method) of participants with solicited local and systemic AEs through 7 days after each study vaccination will be summarised by study vaccine group and the maximum toxicity grade over 7 days after each study vaccination. The duration of solicited local and systemic AEs after each study vaccination will also be summarised by treatment group.

Unsolicited AEs will be coded by preferred term and system organ class using the latest version of the Medical Dictionary for Regulatory Activities and summarised by study vaccine group as well as by severity and relationship to study vaccine. AEs through 49 days after first

study vaccination; all MAAEs through 35 days after first study vaccination; and MAAEs related to study vaccine; SAEs; or AESIs through EOS will be listed separately and summarised by study vaccine group.

Vital sign measurements will be summarised by study vaccine group using descriptive statistics at baseline and following study vaccination.

Concomitant medications will be provided in a data listing with preferred drug name as coded using the World Health Organisation (WHO) drug dictionary.

Interim Analyses

Prior to the final analysis, 2 formal interim analyses of efficacy and futility will be conducted based on the accumulation of approximately 43% (66 events) and 72% (110 events) of the total target number of the primary endpoint (152 events). For these analyses, the data needed to perform the analysis of the primary efficacy endpoint will be cleaned. The interim analyses will be performed by an unblinded Biostatistics and Programming team, and the unblinded statistician will communicate the results of the analyses to the Sponsor in terms of fulfillment or nonfulfillment of the pre-defined success criterion (yes/no).

Based on the communication received from the unblinded statistician, the sponsor may choose to stop the study to unblind the accrued data or to continue the study while maintaining the blind to achieve a more robust safety and efficacy data package for the regulatory submission. Any early stopping for efficacy will be based on the PP-EFF population only. The unblinded statistician and programmer team will be isolated (by firewall) from study personnel. They will complete a review independent of the study team and sponsor. The interim analyses will follow standard group-sequential design using the Lan-DeMets alpha-spending function for O'Brien-Fleming boundary conditions. [Table 7-2](#) summarizes the timing, number of endpoints, and statistical success boundaries at the planned interim analyses and the final analysis.

Planned Analyses Prior to Study Completion:

Analysis of the data will be provided on an ongoing basis for confirming success and to review safety as the study progresses. The statistical analysis plan (SAP) will outline the sequential nature of these reviews.

1. INTRODUCTION

1.1 Background

Coronaviruses are medium sized, enveloped, positive-stranded ribonucleic acid (RNA) viruses, with a characteristic crown-like appearance in electron micrographs due to circumferential studding of the viral envelope with projections comprising the spike (S) protein. There are 4 different strains (229E, OC43, NL63, and HKU1), which are ubiquitous in humans and generally result in mild upper respiratory illnesses and other common cold symptoms including malaise, headache, nasal discharge, sore throat, fever, and cough [Su 2016]. In addition, other coronavirus strains are widespread in animals, where they typically cause enteric disease. These zoonotic coronaviruses have been known to evolve into strains that can infect humans with serious consequences including severe acute respiratory syndrome coronavirus (SARS-CoV) from 2002 to 2003, Middle Eastern Respiratory Syndrome (MERS)-CoV since 2012, and most recently, the novel SARS-CoV-2 since 2019 [Habibzadeh 2020].

In late December of 2019, an outbreak of respiratory disease caused by novel coronavirus (2019 nCoV) was detected in Wuhan, Hubei province, China. The virus' rapidly discerned genetic relationship with the 2002-2003 SARS-CoV has resulted in adoption of the name "SARS-CoV-2," with the disease being referred to as coronavirus disease 2019 (COVID-19). Despite containment efforts since the start of the outbreak, the SARS-CoV-2 has spread rapidly with over 214 countries/territories/areas outside of China reporting laboratory confirmed COVID-19 cases as of 15 May 2020 [WHO, 2020]. On 30 January 2020, the International Health Regulations Emergency Committee of the World Health Organisation (WHO) designated the outbreak as a public health emergency of international concern (PHEIC) and subsequently declared a pandemic on 11 March 2020.

Novavax, Inc. is developing a recombinant vaccine adjuvanted with the saponin-based Matrix-M1™ adjuvant for the prevention of disease caused by SARS-CoV-2. SARS-CoV-2 recombinant (r) spike (S) protein nanoparticle vaccine (SARS-CoV-2 rS) is constructed from the full-length, wild-type SARS-CoV-2 S glycoprotein (GP) based upon the GenBank gene sequence MN908947, nucleotides 21563-25384, from the 2019 SARS-CoV-2 genome. The S protein is a type 1 trimeric glycoprotein of 1,273 amino acids that is produced as an inactive S0 precursor. The S-gene was codon optimised for expression in *Spodoptera frugiperda* (Sf9) insect cells. The SARS-CoV-2 rS nanoparticle vaccine is intended for administration with Matrix-M1 adjuvant, which is a saponin-based adjuvant that has previously been shown to enhance the immunogenicity of other nanoparticle vaccines in nonclinical and clinical studies.

1.2 Nonclinical Experience

In support of the development of SARS-CoV-2 rS, Novavax has obtained nonclinical pharmacology data concerning several SARS-CoV-2 S protein variants, toxicity data concerning SARS-CoV-2 rS with Matrix-M1 adjuvant, and prior toxicity data concerning other viral glycoproteins manufactured in the baculovirus-Sf9 system and formulated with Matrix-M1 adjuvant.

1.2.1 Nonclinical Data from SARS-CoV-2 Spike Protein Constructs that Support SARS-CoV-2 rS Development

Mouse immunogenicity studies were conducted to evaluate several SARS-CoV-2 S protein variants and to select the vaccine candidate [Tian 2020]. The selected vaccine candidate, BV2373 (3Q-2P), was demonstrated to be immunogenic and elicited functional antibodies. For the tested constructs, shallow dose responses with Matrix-M1 adjuvant were observed, suggesting that the adjuvant may be significantly antigen-sparing in large animals and humans.

The candidate SARS-CoV-2 rS vaccine, based on the BV2373 construct, has been evaluated in dose-titration studies in [REDACTED] cynomolgus macaques, and baboons. [REDACTED]

[REDACTED] In cynomolgus macaques, 2 dose regimens of 5 or 25 µg SARS-CoV-2 rS/25 or 50 µg Matrix-M1 adjuvant were also highly immunogenic, resulting in high anti-S IgG levels, high hACE2 binding inhibition titres, and high neutralising antibody responses. The 5 and 25 µg antigen doses gave generally similar responses when administered twice with 50 µg of Matrix-M1 adjuvant. In baboons, which may be more predictive of responses in humans, 5 and 25 µg SARS-CoV-2 rS/50 µg Matrix-M1 adjuvant induced high levels of anti-S IgG, hACE2-binding inhibiting antibodies, and neutralising antibodies. Matrix-M1 adjuvant provided antigen-sparing, and supported induction of functional antibodies. Importantly, Matrix-M1 adjuvanted SARS-CoV-2 rS also appeared to induce strong T helper 1 (Th1) type CD4⁺ T-cell responses to SARS-CoV-2 S protein that included polyfunctional effector phenotypes. Current data in this small baboon study confirms that doses of 5 µg and 25 µg with 50 µg Matrix-M1 are the correct doses to test clinically, with Matrix-M1 adjuvant appearing critical for maximum responses.

Virus challenge studies were performed in mice, [REDACTED] and cynomolgus macaques. In 2 mouse challenge models, immunisation with 1 or 2 doses of SARS-CoV-2 rS/Matrix-M1 adjuvant suppressed viral replication, reduced lung inflammation, and reduced systemic morbidity (weight loss) after SARS-CoV-2 live virus challenge and were not associated with any obvious exacerbation of the inflammatory response to the virus or worsening of clinical outcomes. The best responses were seen in animals receiving 2 doses of adjuvanted vaccine.

[REDACTED]

In cynomolgus macaques, administered with human doses of 5 or 25 µg SARS-CoV-2 rS adjuvanted with 50 µg Matrix-M1, high and comparable levels of anti-S IgG titres and hACE2 receptor binding inhibition titres were detected 21 days after the first immunisation. All of the macaques immunised with any dose or regimen of SARS-CoV-2 rS/Matrix-M1 adjuvant were protected against live virus challenge as evidenced by the reduction of total viral RNA and subgenomic RNA to below the limit of quantitation in bronchoalveolar lavages and nasal swabs.

1.2.2 Nonclinical Data from Other Baculovirus-Sf9-Produced Nanoparticle Vaccines that Support SARS-CoV-2 rS Development

The immunogenicity and protective efficacy of 2002-2003 SARS-CoV S protein and chimeric influenza/SARS-CoV virus-like particle (VLP) vaccines produced in the baculovirus-Sf9 system and administered with and without aluminum hydroxide adjuvants was demonstrated in a mouse challenge study [Liu 2011]. Robust neutralising antibody titres were observed following vaccination, although both antigens required adsorption to aluminum hydroxide for optimal responses. The immunogenicity and protective efficacy of a MERS-CoV S nanoparticle vaccine with and without Matrix-M1 adjuvant was demonstrated in a mouse challenge study [Coleman 2017]. Following vaccination, the MERS-CoV S nanoparticle was immunogenic across all active treatment groups; however, the presence of Matrix-M1 adjuvant induced a 3- to > 10-fold enhancement of the binding and neutralising antibody responses. In addition, Matrix-M1 adjuvant essentially eliminated the antigen dose-response, suggesting the potential for major antigen-sparing and consequent improved manufacturing efficiency and timeliness [Coleman 2017]. The Matrix-M1 adjuvant was also shown to enhance antibody, cellular, and protective immune responses in Balb/c mice administered Zaire ebolavirus (EBOV) GP vaccine with or without Matrix-M1 or aluminum phosphate adjuvants [Bengtsson 2016].

In addition, 3 GLP-compliant toxicology studies in NZW rabbits have been performed with 4 different antigens (influenza hemagglutinin [HA] ± respiratory syncytial virus [RSV] F, Zika virus envelope dimers [ZIKV EnvD], and EBOV GP), in which up to 100 µg Matrix-

M1 adjuvant alone or with antigen was evaluated. These toxicological investigations indicated that baculovirus-Sf9-produced antigens (up to 240 µg total nanoparticle dose) with Matrix-M1 adjuvant (up to 100 µg) were well tolerated in the animals tested with no evidence of toxicity suggestive of any unusual risk or target organ for toxicity. Non-adverse findings, including local injection site inflammation, enlargement of the lymph nodes draining the injection sites, and elevated serum markers of inflammation (including C-reactive protein), were transient and were considered consistent with immune system stimulation consequent to immunisation.

Further details are provided in the SARS-CoV-2 rS Investigator Brochure (IB).

1.3 Clinical Experience

The first clinical study with SARS-CoV-2 rS nanoparticle vaccine is 2019nCoV-101, which is a 2-part, randomised, observer-blinded, placebo-controlled, Phase 1/2 trial. Part 1 (Phase 1) is designed to evaluate the immunogenicity and safety of SARS-CoV-2 rS nanoparticle vaccine with or without Matrix-M1 adjuvant in 131 healthy participants ≥ 18 to ≤ 59 years of age. Results of an interim analysis at Day 35 showed that SARS-CoV-2 rS with Matrix-M1 adjuvant was well tolerated and elicited robust immune responses [Keech 2020]. There were no serious adverse events (SAEs) or adverse events of special interest (AESIs).

Reactogenicity was mainly mild in severity and of short duration (mean ≤ 2 days), with second vaccinations inducing greater local and systemic reactogenicity. The adjuvant significantly enhanced immune responses (anti-S IgG, hACE2 receptor binding inhibition antibody, and neutralising antibody) and was antigen dose-sparing, and the 2 dose 5µg SARS-CoV-2 rS/Matrix-M1 adjuvant induced mean anti-S IgG and neutralising antibody responses that exceeded the mean responses in convalescent sera from COVID-19 patients with clinically significant illnesses. The vaccine also induced antigen-specific T cells with a largely Th1 phenotype.

Part 2 (Phase 2) is designed to evaluate the immunogenicity, safety, and preliminary efficacy of SARS-CoV-2 rS and Matrix-M1 adjuvant in up to 1,500 healthy adults ≥ 18 to ≤ 84 years of age with more co-morbidities than the participant population in Part 1 of the study.

[REDACTED]

Novavax has, in its internally-sponsored clinical trials, tested baculovirus-Sf9-produced nanoparticle vaccines in 14,848 participants comprising older adults, young adults, and a limited number of children 2 to 5 years of age; and also including 3,075 pregnant women,

with acceptable safety. Matrix-M adjuvant has been given to 4,311 humans (of which, approximately 2,657 humans received nanoparticle vaccine) with acceptable short-term reactivity, and an unremarkable long-term safety profile.

Further details on the clinical experience of the study vaccine can be found in the SARS-CoV-2 rS IB.

1.4 Rationale for Study

Both nonclinical and early clinical data to date have supported clinical development of SARS-CoV-2 rS and Matrix-M1 adjuvant as a potential vaccine against SARS-CoV-2. In rodent and nonhuman primate (NHP) challenge models, SARS-CoV-2 rS and Matrix-M1 adjuvant induced high titres of antibodies measured against anti-S protein and hACE2 receptor binding and achieved neutralisation of wild-type virus that exceeded the magnitude of responses measured in COVID-19 human convalescent sera and provided protection against SARS-CoV-2 challenge [Tian 2020; Mandolesi 2020; Guebre-Xabier 2020]. Notably in NHP studies, clinical doses of vaccine (5- and 25- μ g SARS-CoV-2 rS/50- μ g Matrix-M1) resulted in sterile immunity in the lungs and nasal passage following wild-type virus challenge, suggesting that the vaccine may both protect against upper and lower respiratory tract disease and interrupt transmission [Guebre-Xabier 2020].

Results from a Day 35 interim analysis of Part 1 (Phase 1) of Study 2019nCoV-101 indicate that in healthy adult participants 18 to 59 years of age two-dose regimens of 5- and 25- μ g SARS-CoV-2 rS/50 μ g Matrix-M1 (on Days 0 and 21) were well tolerated and induced the most robust immune responses with high levels of neutralising antibodies that closely correlated with anti-spike IgG [Keech 2020]. Furthermore, neutralising antibody responses following second vaccination were of the magnitude seen in convalescent serum from symptomatic COVID-19 patients and exceeded overall convalescent sera geometric mean titres (GMTs) by four-fold. The benefit of Matrix-M1 adjuvant was clear in the magnitude of the antibody and T-cell response, induction of functional antibodies, and dose sparing.

A Phase 2 clinical program is underway and will provide safety and immunogenicity results in older participants (> 60 years of age) and participants with comorbidities. [REDACTED]

[REDACTED] combining the current nonclinical and clinical data with positive Phase 1/2 data provide the impetus for early initiation of the Phase 3 clinical development program in the context of the current public health pandemic crisis.

The purpose of this study is to evaluate the efficacy, safety, and immunogenicity of SARS-CoV-2 rS with Matrix-M1 adjuvant in adults 18-84 years of age (inclusive). The study will be conducted at anticipated high COVID-19 transmission areas in the United Kingdom (UK). The information provided in this study will inform progression of the study vaccine, to determine efficacy of the study vaccine to prevent COVID-19 in the general population, in participants regardless of serostatus, in participants who have required medical intervention,

and in participants with mild or asymptomatic infections. The study will determine the safety of the study vaccine to use in the general population and to ensure that it elicits a robust immune response.

1.5 Rationale for Dose Selection

As previously described, clinical doses of vaccine and adjuvant (5- and 25- μ g SARS-CoV-2 rS/50- μ g Matrix-M1) resulted in sterile immunity in the lungs and nasal passage following wild-type virus challenge in NHP, suggesting that the vaccine may both protect against upper and lower respiratory tract disease and interrupt transmission [[Guebre-Xabier 2020](#)]. These doses are being evaluated in Part 1 of Study 2019nCoV-101 in 131 healthy adult participants ≥ 18 to ≤ 59 years of age and in Part 2 of Study 2019nCoV-101 in up to 1,500 participants ≥ 18 to ≤ 84 years of age, including participants with comorbidities. Results from the Part 1 Day 35 interim analysis support either dose of SARS-CoV-2 rS/Matrix-M1 in terms of safety and immunology, with the lower dose (5 μ g) offering advantages in regards to dose sparing. All study vaccinations will be administered on an outpatient basis by designated site personnel in a way to maintain the blind. Any pharmacy preparation with unblinded product will require unblinded site personnel who will not otherwise be involved in the study procedures or observation of participants.

1.6 Benefit-Risk Assessment

The SARS-CoV-2 rS nanoparticle vaccine contains purified protein antigens. It cannot replicate, nor can it cause COVID-19. However, in common with all vaccines produced in cell culture or other systems, the SARS-CoV-2 rS nanoparticle vaccine contains residual non-vaccine proteins derived from the production system, and sensitisation to these, or the SARS-CoV-2 S protein itself, may theoretically occur. While the occurrence of immediate hypersensitivity is possible with the administration of any vaccine, whether licensed or in development, no such reactions have been observed in any of these clinical trials to date. As clinical data become available with increased exposure, it is possible that this profile may change.

The risk for enhanced COVID-19 in immunised participants is a theoretical risk. Enhanced disease in coronavirus vaccine-immunised animals after live virus challenge has been demonstrated in nonclinical studies of several, but not all, coronavirus vaccine candidates. There is currently no evidence for immunoenhancement in nonclinical testing of SARS-CoV-2 rS or other Novavax baculovirus-Sf9-based vaccines taken into nonclinical evaluation or clinical trials.

No risks have been identified in nonclinical or early clinical testing of SARS-CoV-2 or other coronavirus vaccines (SARS-CoV and MERS-CoV) developed using the baculovirus-Sf9 system to date. In supportive toxicology studies with other viral GP nanoparticle vaccines developed using the baculovirus-Sf9 system with different antigens, findings were generally consistent with an immune response to the vaccine formulations. These toxicological

investigations indicated that baculovirus-Sf9-produced antigens (up to 240 µg total nanoparticle dose) with Matrix-M1 adjuvant (up to 100 µg) were well tolerated in the animal and antigen system tested with no evidence of toxicity suggestive of any unusual risk or target organ for toxicity. Non-adverse findings, including local injection site inflammation and serum chemical markers of inflammation (such as C-reactive protein), were transient and considered consistent with immune system stimulation consequent to immunisation.

Findings to date suggest that SARS-CoV-2 rS when administered with or without Matrix-M1 adjuvant can be reasonably expected to demonstrate an acceptable safety profile in healthy adult participants aged ≤ 59 years. Novavax baculovirus-Sf9-produced nanoparticle vaccines comprising viral glycoproteins, with and without Matrix-M1 or aluminum adjuvants, have been shown to induce robust and protective immune responses in relevant animal models to influenza HAs, RSV F protein, SARS-CoV and MERS-CoV S proteins, rabies GP, and EBOV GP. In addition, the Novavax SARS-CoV-2 candidate adsorbed to aluminum phosphate has induced antibodies in pregnant women which, when transferred transplacentally, were associated with reduced rates of SARS-CoV-2 lower respiratory tract infections in their infants during the first 90 to 180 days of life. The goal of this program is to investigate the efficacy, safety, and immunogenicity of the SARS-CoV-2 rS and Matrix-M1 adjuvant.

Further details are provided in the SARS-CoV-2 rS IB.

2. STUDY OBJECTIVES AND ENDPOINTS

2.1 Study Objectives

2.1.1 Primary Objective

- To demonstrate the efficacy of SARS-CoV-2 rS with Matrix-M1 adjuvant in the prevention of virologically confirmed (by polymerase chain reaction [PCR] to SARS-CoV-2), symptomatic COVID-19, when given as a 2-dose vaccination regimen, as compared to placebo, in serologically negative (to SARS-CoV-2) adult participants.

2.1.2 Secondary Objectives

- To demonstrate the efficacy of SARS-CoV-2 rS with Matrix-M1 adjuvant in the prevention of virologically confirmed (by PCR to SARS-CoV-2), symptomatic COVID-19, when given as a 2-dose vaccination regimen, as compared to placebo, in adult participants regardless of their serostatus at baseline.
- To assess the efficacy of SARS-CoV-2 rS with Matrix-M1 adjuvant on SARS-CoV-2 seropositive adult participants requiring specific medical interventions as compared to placebo.
- To assess the efficacy of SARS-CoV-2 rS with Matrix-M1 adjuvant on mild COVID-19 symptoms as compared to placebo.
- To assess the efficacy of SARS-CoV-2 rS with Matrix-M1 adjuvant on occurrence of asymptomatic or undetected infections with SARS-CoV-2 as compared to placebo.
- In a subset of adult participants, to evaluate the immunogenicity of SARS-CoV-2 rS with Matrix-M1 adjuvant as compared to placebo.
- To evaluate safety in terms of SAEs and medically attended adverse events (MAAEs) related to study vaccination in all adult participants during the entire study period.
- To evaluate safety in terms of AESI, which encompasses potential immune-mediated medical conditions (PIMMCs) and AESIs relevant to COVID-19, including possible vaccine-enhanced disease, in all adult participants at any time after the first dose.
- In a subset of adult participants, to evaluate the safety and reactogenicity in terms of solicited local and systemic adverse events (AEs) for 7 days after each study vaccination.
- To evaluate safety in terms of all MAAEs for 14 days after second vaccination and unsolicited AEs for 21 days after first study vaccination and 28 days after second study vaccination.

2.1.3 Exploratory Objective

- In a subset of adult participants, to evaluate the safety and immunogenicity of SARS-CoV-2 rS with Matrix-M1 adjuvant when co-administered with a licensed seasonal influenza vaccine.

2.2 Study Endpoints

2.2.1 Primary Endpoints

- First occurrence of virologically confirmed (by PCR to SARS-CoV-2), symptomatic mild, moderate, or severe COVID-19 (Table 2-1) with onset at least 7 days after second study vaccination (e.g., Day 28) in serologically negative (to SARS-CoV-2) adult participants at baseline until the endpoint-driven efficacy analysis is triggered by the occurrence of a prespecified number of blinded endpoints.

-

Table 2-1: Endpoint Definitions of COVID-19 Severity

COVID-19 Severity	Endpoint Definitions
Mild	<p>≥ 1 of:</p> <ul style="list-style-type: none"> • Fever (defined by subjective or objective measure, regardless of use of anti-pyretic medications) • New onset cough • ≥ 2 COVID-19 respiratory/non-respiratory symptoms in Table 2-2 <p>AND</p> <ul style="list-style-type: none"> • Does not meet criteria for moderate or severe disease
Moderate	<p>≥ 1 of:</p> <ul style="list-style-type: none"> • Fever (defined by subjective or objective measure, regardless of use of anti-pyretic medications) + any 2 COVID-19 symptoms in Table 2-2 for ≥ 3 days (need not be contiguous days) • High fever (≥ 38.4°C) for ≥ 3 days (need not be contiguous days) • Any evidence of significant LRTI: <ul style="list-style-type: none"> – Shortness of breath (or breathlessness or difficulty breathing) with or without exertion (greater than baseline) – Tachypnea: 20 to 29 breaths per minute at rest – SpO2: 94% to 95% on room air – Abnormal chest x-ray or chest CT consistent with pneumonia or LRTI – Adventitious sounds on lung auscultation (e.g., crackles/rales, wheeze, rhonchi, pleural rub, stridor) <p>AND</p> <ul style="list-style-type: none"> • Does not meet criteria for severe disease

Table 2-1: Endpoint Definitions of COVID-19 Severity

COVID-19 Severity	Endpoint Definitions
Severe	<p>≥ 1 of:</p> <ul style="list-style-type: none"> • Tachypnea: ≥ 30 breaths per minute at rest • Resting heart rate ≥ 125 beats per minute • SpO₂: ≤ 93% on room air or PAO₂/FiO₂ < 300 • High flow oxygen therapy or NIV/NIPPV (e.g., CPAP or BiPAP) • Mechanical ventilation or ECMO • One or more major organ system dysfunction or failure (e.g., cardiac/circulatory, pulmonary, renal, hepatic, and/or neurological, to be defined by diagnostic testing/clinical syndrome/interventions), including any of the following: <ul style="list-style-type: none"> ○ ARDS ○ Acute renal failure ○ Acute hepatic failure ○ Acute right or left heart failure ○ Septic or cardiogenic shock (with shock defined as SBP < 90 mm Hg OR DBP < 60 mm Hg) ○ Acute stroke (ischemic or hemorrhagic) ○ Acute thrombotic event: AMI, DVT, PE ○ Requirement for: vasopressors, systemic corticosteroids, or hemodialysis. • Admission to an ICU • Death

Abbreviations: AMI = acute myocardial infarction; ARDS = acute respiratory distress syndrome; BiPAP = bi-level positive airway pressure; CPAP = continuous positive air pressure; CT = computed tomography; DBP = diastolic blood pressure; DVT = deep vein thrombosis; ECMO = extracorporeal membrane oxygenation; FiO₂ = fraction of inspired oxygen; ICU = intensive care unit; LRTI = lower respiratory tract infection; NIV = non-invasive ventilation; NIPPV = non-invasive positive pressure ventilation; PAO₂ = partial pressure of oxygen in the alveolus; PE = pulmonary embolism; SBP = systolic blood pressure; SpO₂ = oxygen saturation.

Table 2-2: Qualifying Symptoms of Suspected COVID-19

<ul style="list-style-type: none"> • Fever • New onset cough • New onset or worsening of shortness of breath or difficulty breathing compared to baseline • New onset fatigue • New onset generalised muscle or body aches • New onset headache lasting ≥ 48 hours • New loss of taste or smell • Acute onset of sore throat, congestion, and runny nose • New onset nausea, vomiting, or diarrhea lasting ≥ 48 hours •

Abbreviations: COVID-19 = coronavirus disease 2019.

2.2.2 Secondary Endpoints

2.2.2.1 Key Secondary Endpoint

- First occurrence of virologically confirmed (by PCR to SARS-CoV-2), symptomatic moderate or severe COVID-19 with onset at least 7 days after second study vaccination (e.g., Day 28) in serologically negative (to SARS-CoV-2) adult participants at baseline until the endpoint-driven efficacy analysis is triggered by the occurrence of a prespecified number of blinded endpoints.

2.2.2.2 Other Secondary Endpoints

- First occurrence of virologically confirmed (by PCR to SARS-CoV-2), symptomatic mild, moderate, or severe COVID-19, with onset at least 7 days after second study vaccination (e.g., Day 28) in adult participants regardless of their serostatus at baseline.
- First occurrence of COVID-19 requiring hospitalisation, intensive care unit (ICU) admission or mechanical ventilation linked to any virologically confirmed (by PCR to SARS-CoV-2) COVID-19 with onset at least 7 days after second study vaccination (e.g., Day 28) in adult participants regardless of their serostatus at baseline.
- First occurrence of virologically confirmed (by PCR to SARS-CoV-2), symptomatic mild COVID-19 (with no progression to moderate or severe COVID-19 during the course of the COVID-19 episode) with onset at least 7 days after second study vaccination (e.g., Day 28) in adult participants regardless of their serostatus at baseline.
- First occurrence of laboratory-confirmed (by PCR or nucleocapsid [N] protein serology to SARS-CoV-2) symptomatic or asymptomatic COVID-19 with onset at least 7 days after second study vaccination (e.g., Day 28) in adult participants regardless of their serostatus at baseline.
- Analysis of antibodies binding to the SARS-CoV-2 spike (S) protein by enzyme-linked immunosorbent assay (ELISA) at Day 0 (baseline) and Day 35 (14 days after second study vaccination).
- The occurrence and relationship to study vaccination of SAEs and MAAEs related to study vaccination (in all adult participants) during the entire study period.
- The occurrence and relationship to study vaccination of AESIs and PIMMCs (in all adult participants) during the entire study period.
- The occurrence and severity of reactogenicity in terms of solicited local and systemic AEs (in all sub-study participants) for 7 days after each study vaccination.

- The occurrence, severity, and relationship to study vaccination of all MAAEs for 14 days after second vaccination and unsolicited AEs (in all adult participants) for 21 days after first study vaccination and 28 days after second study vaccination.

2.2.3 Exploratory Endpoints

- First occurrence of virologically confirmed (by PCR to SARS-CoV-2), symptomatic mild, moderate, or severe COVID-19 with onset at least 14 days after first study vaccination (e.g., Day 14) in serologically negative (to SARS-CoV-2) adult participants at baseline until the endpoint-driven efficacy analysis is triggered by the occurrence of a prespecified number of blinded endpoints.
- Any occurrence of serologic conversion (by serology to SARS-CoV-2 N protein) between baseline and 1 year after last study vaccination in adult participants seronegative at baseline.
- Analysis of the proportion of adult participants with evidence of seroconversion as demonstrated by antibodies to the SARS-CoV-2 S protein by ELISA at Day 35 (14 days after second study vaccination).
- Analysis of the cell-mediated immune responses (for example, as measured by enzyme-linked immune absorbent spot (ELISpot) ± intracellular cytokine staining) on Days 0 (baseline) and 35 (14 days after second study vaccination).
- SARS-CoV-2 neutralisation as measured by virus neutralisation assay (VNA; wild-type virus and/or pseudovirion expressing SARS-CoV-2 S protein) at Day 0 (baseline) and Day 35 (14 days after second study vaccination).
- Analysis of the safety and immunogenicity of SARS-CoV-2 rS with Matrix-M1 adjuvant when co-administered with seasonal influenza vaccine in a subset population.

3. STUDY DESIGN

This is a Phase 3, multi-centre, randomised, observer-blind, placebo-controlled study evaluating the efficacy, safety, and immunogenicity of SARS-CoV-2 rS with Matrix-M1 adjuvant in adult participants 18 to 84 years of age (inclusive) in the UK. Every effort will be made to identify sites of high SARS-CoV-2 activity, and populations within these sites who are at high risk of exposure to the virus will be enrolled such that the incidence of COVID-19 in the study will be higher than 1% and the sample size and enrolment period may be reduced.

After signing informed consent, participants may be screened within a window of up to approximately 30 days. Nose/throat samples may be taken during the screening period to detect SARS-CoV-2 by PCR, if the participant has any COVID-19 symptoms or significant exposure history.

Approximately 15,000 male and female adult participants 18 to 84 years of age (inclusive) with and without relevant comorbidities are planned for the study. An effort will be made to enrol a target of at least 25% of participants who are ≥ 65 years of age as well as prioritising other groups that are most affected by COVID-19, including racial and ethnic minorities. This will be under the assumption that the annual incidence of symptomatic COVID-19 will be approximately 1% to 5%.

The sample size may be adjusted by the sponsor during the study, based on blinded data, to ensure sufficient power at the time of the primary analysis. Details on the possible sample-size reassessment will be described in the statistical analysis plan (SAP).

On Day 0, nose/throat samples will be taken to detect PCR for SARS-CoV-2 and blood samples will be taken to detect any existing SARS-CoV-2 antibodies at baseline. Participants will be randomised in a 1:1 ratio via block randomisation to receive 2 intramuscular (IM) injections of the SARS-CoV-2 rS with Matrix-M1 adjuvant or placebo, as described in [Figure 1](#).

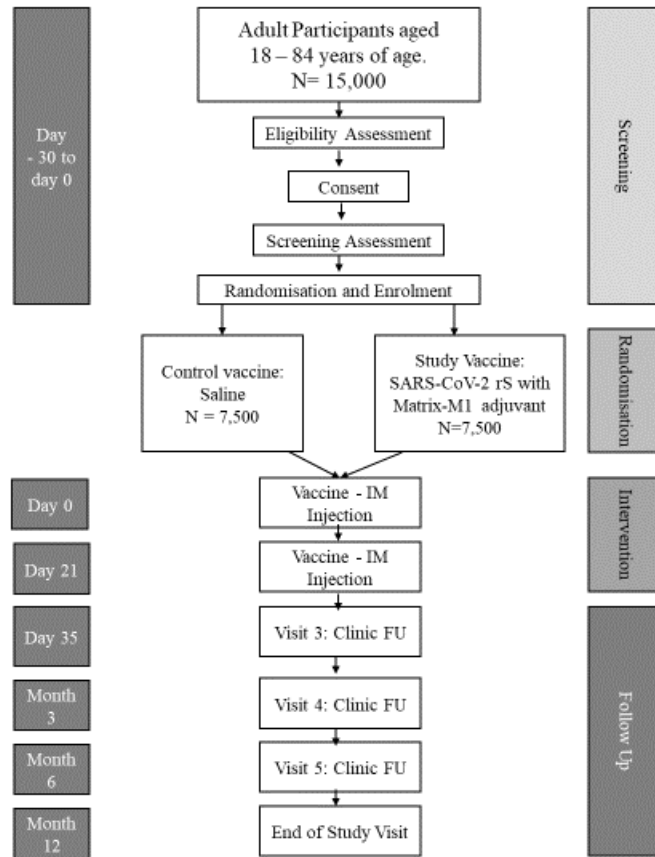

Figure 1: Trial Schema

FU = follow-up; IM = intramuscular; N = number of participants.

Randomisation will be stratified by site and by age ≥ 65 years. In addition, there will not be specific age sub-stratification recruitment targets within the ≥ 65 -year age group, but through site recruitment; the aim is to allow a generally representative age distribution overall.

The study will consist of the screening period (Days -30 to 0); study vaccination Days 0 and 21 (+7-day window); and outpatient study visits on Day 0, Day 21 (+ 7 days), and Day 35 (14 days minimum after second study vaccination [+ 7 days]); and at 3, 6, and 12 months (± 15 days) after last study vaccination.

The duration of individual participation, including screening, will be a maximum of 1 year after second study vaccination (Day 386 ± 15 days). This will be an event-driven study for the assessment of vaccine efficacy (VE) and will end when a sufficient number of events

have been observed, yet all participants will be followed for the entire study duration for safety endpoints.

A licensed seasonal influenza co-administration sub-study will be conducted in the first 400 participants who meet the additional inclusion criteria for this study. Participants may be enrolled at selected study sites due to the availability of seasonal influenza vaccine. After being randomised to receive IM injections of SARS-CoV-2 rS with Matrix-M1 adjuvant or placebo, sub-study participants will receive a licensed seasonal influenza vaccine on Day 0 in the opposite deltoid. These participants will be part of the solicited AE safety subset analysis.

Given that this study and others will enrol during the influenza virus season and that the highest at-risk population, namely the elderly and adults with comorbid conditions for influenza mirrors that of SARS-CoV-2, a co-vaccination sub-study is included. This sub-group will undergo the same safety and efficacy evaluations as the entire study population. In addition, the entire sub-study will have reactogenicity assessed. This group must not have had a current season licensed influenza vaccine and have no prior history of allergy or severe reaction to seasonal influenza vaccine. To assess the possible impact of the study vaccine on the immunogenicity of the influenza vaccine, this group will also have a hemagglutination inhibition assay (HAI) performed.

A global Safety Monitoring Committee (SMC) was convened to oversee the safety of the ongoing Phase 1/2 study (Protocol 2019nCoV-101) and will oversee one or more additional studies across the SARS-CoV-2 rS vaccine program. A separate SMC will be convened for this study. The designated SMC will monitor the safety of participants in the study and will follow an SMC charter. The SMC will review blinded and unblinded safety and reactogenicity data. The SMC will also review sufficient clinical event data to ensure detection of any evidence of enhanced disease. The SMC will convene to perform safety reviews on a scheduled basis, for immediate concerns regarding safety observations during this study, and as needed.

3.1 Study Vaccination Pause Rules

Study vaccination pause rules based on reactogenicity, AEs, and SAEs related to study participation will be in place to monitor participant safety during the study.

AEs meeting any one of the following criteria will result in a hold being placed on subsequent study vaccinations pending further review by the SMC at the direction of the SMC chair:

- Any toxicity grade 3 or higher (severe or potentially life-threatening) solicited (local or systemic) single AE term occurring in $\geq 10\%$ of participants (after a minimum of 100 subjects are enrolled) in the SARS-CoV-2 rS with Matrix-M1 adjuvant group within the first 7 days after study vaccination.

- Any severe unsolicited single AE preferred term for which the investigator assesses as related that occurs in $\geq 5\%$ of participants (after a minimum of 100 subjects are enrolled) in the SARS-CoV-2 rS with Matrix-M1 adjuvant group, within the first 7 days after study vaccination.

In addition, any SAE assessed as related to vaccine (final assessment by the sponsor) will be reported by the sponsor to the SMC Chair as soon as possible, and within 24 hours of the sponsor's awareness of the event. Based on this initial report of the event to the SMC Chair, the Chair may advise the sponsor to immediately pause enrolment and further dosing in either some or all subjects in the study and to convene an ad hoc meeting, or make alternative recommendations. The SMC Charter defines processes for how this review will occur and how the Chair's recommendations will be documented.

The sponsor, along with medical monitor, may request an SMC review for any safety concerns that may arise in the study, even if they are not associated with any specific pause rule; for example, any SAE for which causality is at least possibly related.

The 400 subject influenza vaccine co-administration study will utilize the same pause rules with one difference due to the expectation of greater reactogenicity and the small size:

- Any grade 3 or higher (severe or potentially life-threatening) solicited (local or systemic) single AE term occurring in $\geq 20\%$ of participants in the SARS-CoV-2 rS with Matrix-M1 adjuvant plus seasonal influenza vaccine group, within the first 7 days after study vaccination.

3.2 Schedule of Events (SOE)

Table 3-1 lists the study procedures that will be performed during the study. Detailed descriptions of each visit are presented in Section 6.1.

Table 3-1 Schedule of Events

SAEs ^w	X	X	X	X	X	X	X	
AESI ^x		X	X	X	X	X	X	
EOS form ^y							X	

Abbreviations: AE = adverse event; AESI = adverse event(s) of special interest; COVID-19 = coronavirus disease 2019; ELISA = enzyme-linked immunosorbent assay; ELISpot = enzyme-linked immune sorbent spot; EOS = end of study; HAI = hemagglutinin assay inhibition; HEENT = head, eye, ear, nose, and throat (exam); ID = identification; MAAE = medically attended adverse event; N = nucleocapsid; PCR = polymerase chain reaction; PIMMC = potential immune-mediated medical conditions; S = spike protein; SAE = serious adverse event; SAP = statistical analysis plan; SARS-CoV-2 = severe acute respiratory syndrome coronavirus 2; WOCBA = women of childbearing age.

- ^a The Screening visit and Day 0 visit may be combined if feasible at any given study site.
- ^b Days relative to study vaccination are only estimates because the window allowance is not inclusive. Should a study pause occur, visits/windows will be adjusted to allow participants to continue without protocol deviation. Visit schedules after second study vaccination are calculated relative to the day the study vaccinations were received.
- ^c EOS visit. Should participants decide to terminate early, an EOS telephone call will occur to collect the maximum safety data possible.
- ^d Including prior and concomitant medical conditions, recent vaccinations (≤ 90 days), and significant surgical procedures.
- ^e Specific exclusions to study vaccination will be assessed before any vaccination. Waivers to enrolling participants with exclusions will not be given.
- ^f Performed prior to study vaccination.
- ^g Screening only. Including date of birth (day, month, and year), sex, race, ethnicity, weight, and height.
- ^h Recent and current medications at the time of screening to be reviewed to ensure eligibility criteria are fulfilled. Concomitant medications include all medications (including vaccines) taken by the participant.
- ⁱ Including respiratory rate, blood pressure, pulse rate, pulse oximetry and oral temperature (or via forehead/ear reader). On study vaccination days, vital sign measurements will be collected once before study vaccination to ensure participant has no evidence of fever prior to study vaccination. Vital sign measurements will also be collected once again, approximately 15 to 30 minutes after study vaccination, to check for any reactions to the vaccine.
- ^j Women of childbearing potential only. A urine pregnancy test will be performed at Screening and prior to each study vaccination. A positive urine pregnancy test at any time will result in the participant not receiving any further study vaccination. A positive urine pregnancy test at Screening will result in screen failure.
- ^k Examination at screening to include height and weight; HEENT, neck, thyroid, lungs, heart, cardiovascular, abdomen, lymph nodes of the upper extremities and neck; and musculoskeletal system/extremities to allow for study vaccination; symptom-directed (targeted) physical examination at all other scheduled time points but always to include lymphatic assessment of injected upper extremity on study vaccination days. Physical examination on study vaccination visits must be done prior to vaccination. Interim physical examinations will be performed at any unscheduled visit at the discretion of the investigator, if necessary.

Table 3-1 Schedule of Events

Study Period:	Screening Period ^a	Clinic Visits			COVID-19 Surveillance Visits (Unscheduled)	Months After Last Study Vaccination		
Study Day:	-30 to 0	0 ^a	21	35			3	6
Window (days): ^b	-	0	+7	+7		± 15	± 15	± 15
Minimum days following most recent study vaccination: ^b	-	0	21	14		-	-	-
Study Visit:	Screening	1	2	3		4	5	EOS ^c

^l Samples will be collected at Screening only if the participant has any COVID-19 symptoms or significant exposure history. If a participant has a positive PCR prior to enrolment, they will be considered a screen failure. Samples will be collected on Day 0 and the method of collection will be taught. Participants found to be SARS-CoV-2 positive on Day 0 will be excluded from some analyses of the study as per the SAP. Samples may be collected on Day 21 only if the participant has any COVID-19 symptoms or significant exposure history between Days 0 and 21. Results of that test are not required for study vaccination, but participants who are symptomatic may have the second study vaccination delayed per protocol. Participants found to be SARS-CoV-2 positive on Day 21 will be excluded from some analyses of the study as per the SAP.

^m The ELISA for anti-S protein serology will be performed in the approximately 900 participants in the Anti-S Protein Serology Subset.

ⁿ The neutralising antibody assay will be performed in the approximately 900 participants in the Neutralisation Assay Subset.

^o The HAI assay will be performed in the approximately 400 participants in the licensed seasonal influenza co-administration sub-study.

^p Cell-mediated immune responses, as assessed by ELISpot ± intracellular cytokine staining, will be performed in approximately 450 participants in the Cell-mediated Assay Subset.

^q Study vaccination on Day 0 will consist of study vaccine plus, in the seasonal influenza vaccine co-administration sub-study, a single dose of licensed influenza vaccine. Study vaccination on Day 21 will consist of study vaccine.

^r Solicited AEs (e.g., local and general systemic reactogenicity symptoms) will be captured in the Safety Subset of approximately 2,000 participants and in the first approximately 400 participants who qualify for the seasonal influenza vaccine co-administration sub-study. On study vaccination days, participants will remain in clinic for at least 30 minutes to be monitored for any severe reactogenicity. Severe reactions will be noted as AEs on day of study vaccination.

^s Participants will monitor for COVID-19 symptoms. This will include provision of a Study ID Card that provides details on study participation, study site contact information and assessment of symptoms of suspected COVID-19 (see Table 2-2). Instructions to participants to contact the study site within 24 hours for symptoms of suspected COVID-19 will be given. A participant with suspected or confirmed COVID-19 will be asked to complete a COVID-19 symptom diary for 10 days. The Study ID Card should be presented to healthcare providers not affiliated with the study who encounter participants with symptoms of suspected COVID-19.

^t A participant with suspected or confirmed COVID-19 will be asked to complete the COVID-19 symptom diary. Participants should start the diary on their first day of symptoms and complete this diary daily for a minimum of 10 days even if their symptoms have resolved and regardless of any SARS-CoV-2 PCR results. They should continue the diary beyond 10 days if they have any ongoing symptoms related to the episode and should continue to do so until all symptoms have resolved.

^u All unsolicited AEs are to be reported from the time of first study vaccination until 21 days after first study vaccination and 28 days after second study vaccination in all participants.

^v MAAEs are to be collected from the time of first study vaccination until Day 35, and MAAEs assessed as related to study vaccination from the time of first study vaccination until completion of the participant’s last study-related procedure.

^w SAEs are to be collected from the time of informed consent until completion of the participant’s last study-related procedure.

^x AESI: To include PIMMC and AEs related to COVID-19 are to be collected from the time of first study vaccination until completion of the participant’s last study-related procedure.

^y EOS form will be completed for all participants, including participants who are terminated early.

Table 3-1 Schedule of Events

Study Period:	Screening Period ^a	Clinic Visits			Months After Last Study Vaccination			
Study Day:	-30 to 0	0^a	21	35	COVID-19 Surveillance Visits (Unscheduled)	3	6	12
Window (days):^b	-	0	+7	+7		± 15	± 15	± 15
Minimum days following most recent study vaccination:^b	-	0	21	14		-	-	-
Study Visit:	Screening	1	2	3		4	5	EOS ^c

^z Samples will be self-collected by the participants in an effort to determine if the current symptoms are due to SARS-CoV-2 infection. Approximately 24 hours after the onset of symptoms the participants will swab themselves daily for up to 3 days but only until the point that 1 of the samples tests positive for SARS-CoV-2.

4. STUDY POPULATION

Approximately 15,000 male and female adult participants 18 to 84 years of age (inclusive) with and without relevant comorbidities will be randomised in a 1:1 ratio via block randomisation to receive 2 intramuscular (IM) injections of SARS-CoV-2 rS with Matrix-M1 adjuvant or placebo in a blinded fashion in up to 28 sites across the UK.

4.1 Inclusion Criteria

Each participant must meet all of the following criteria to be enrolled in this study:

1. Adult males or females aged 18 to 84 years (inclusive) at screening.
2. Able and willing (in the investigator's opinion) to comply with all study requirements.
3. Willing to allow the investigators to discuss the volunteer's medical history with their General Practitioner and access all medical records when relevant to study procedures.
4. Willing and able to give informed consent prior to study enrolment.
5. Female participants of childbearing potential (defined as any female who has experienced menarche and who is NOT surgically sterile [i.e., hysterectomy, bilateral tubal ligation, or bilateral oophorectomy] or postmenopausal [defined as amenorrhea at least 12 consecutive months or > 1 documented plasma follicle-stimulating hormone level \geq 40 mIU/mL]) must agree to be heterosexually inactive from at least 28 days prior to enrolment and through 3 months after the last study vaccination OR agree to consistently use any of the following methods of contraception from at least 28 days prior to enrolment and through 3 months after the last study vaccination:
 - a. Condoms (male or female)
 - b. Diaphragm with spermicide
 - c. Cervical cap with spermicide
 - d. Intrauterine device
 - e. Oral or patch contraceptives
 - f. Norplant[®], Depo-Provera[®], or other in country regulatory-approved contraceptive method that is designed to protect against pregnancy
 - g. Abstinence, as a form of contraception, is acceptable if in line with the participant's lifestyle (other approaches to abstinence are not acceptable)

NOTE: Periodic abstinence (e.g., calendar, ovulation, symptothermal, post-ovulation methods) and withdrawal are not acceptable methods of contraception.
6. Room air oxygen saturation > 95% at Screening/Day 0.

Seasonal Influenza Vaccine Co-Administration Sub-Study Only

7. Participant should not have received a current season influenza vaccine, have no contraindication to the specific vaccine to be administered in the study, and no prior history of allergy or severe reaction to seasonal influenza vaccines.

4.2 Exclusion Criteria

Participants meeting any of the following criteria will be excluded from the study:

1. Participation in COVID-19 prophylactic drug trials for the duration of the study.
2. Future participation in SARS-CoV-2 serological surveys where participants are informed of their serostatus for the duration of the study.
3. Participation in research involving an investigational product (drug/biologic/device) within 45 days prior to first study vaccination.
4. History of laboratory-confirmed (by PCR or serology to SARS-CoV-2) COVID-19 infection at any time prior to randomisation.
5. Administration of immunoglobulins and/or any blood products within the 3 months preceding the planned administration of the study vaccine candidate.
6. Any confirmed or suspected immunosuppressive or immunodeficient state; chronic administration (defined as more than 14 continuous days) of immunosuppressant medication within the past 3 months, except topical steroids or short-term oral steroids (course lasting \leq 14 days).

NOTE: An immunosuppressant dose of glucocorticoid is defined as a systemic dose \geq 10 mg of prednisone per day or equivalent. The use of topical, inhaled, and nasal glucocorticoids will be permitted if other chronic disease conditions are not exclusionary. Human immunodeficiency syndrome (HIV)-positive participants receiving highly active antiretroviral therapy and a history within 6 months of screening of viral load $<$ 1000 copies/mL or CD4 count $>$ 300 cells/mm³ would be eligible.

7. History of allergic disease or reactions likely to be exacerbated by any component of the study vaccines.
8. Any history of anaphylaxis to any prior vaccine.
9. Pregnancy, lactation, or willingness/intention to become pregnant within 3 months following the last study vaccination.
10. Current diagnosis of or treatment for cancer (except basal cell carcinoma of the skin and cervical carcinoma in situ, at the discretion of the investigator).
11. Bleeding disorder (e.g., factor deficiency, coagulopathy or platelet disorder), or prior history of significant bleeding or bruising following IM injections or venepuncture.

12. Continuous use of anticoagulants, such as coumarins and related anticoagulants (i.e., warfarin) or novel oral anticoagulants/anti-platelet agents.
NOTE: The use of ≤ 325 mg of aspirin per day as prophylaxis is permitted.
13. Suspected or known current alcohol or drug dependency.
14. Study team member or first-degree relative of any study team member (inclusive of sponsor, contract research organisation (CRO), and site personnel involved in the study).
15. Participants who are having any current workup of undiagnosed illness within the last 8 weeks that is either participant-reported or has been clinician-assessed, which could lead to a new condition or diagnosis.
16. Received any live vaccine within 4 weeks or **any vaccine** (excluding influenza) within 2 weeks prior to first study vaccination or any licensed influenza vaccine within 1 week prior to first study vaccination or plans to receive any vaccine from these time periods until 28 days after second study vaccination.
NOTE: An influenza co-administration sub-study will occur in which 400 participants will receive a single dose of seasonal influenza vaccine at the same time as first study vaccination. In addition, a licensed seasonal influenza vaccine may be given 7 days after each vaccination but should not be given within 7 days prior to second vaccination.
17. Have clinically significant chronic cardiovascular, endocrine, gastrointestinal, hepatic (including hepatitis B and C), renal, neurological, respiratory, psychiatric or other medical disorders not excluded by other exclusion criteria, that are assessed by the investigator as being clinically unstable within the prior 4 weeks as evidenced by:
 - a. Hospitalisation for the condition, including day surgical interventions.
 - b. New significant organ function deterioration.
 - c. Needing addition of new treatments or major dose adjustments of current treatments (mild or moderate well-controlled comorbidities are allowed).
18. History of chronic neurological disorders that have required prior specialist physician review for diagnosis and management (such as multiple sclerosis, dementia, transient ischemic attacks, Parkinson's disease, degenerative neurological conditions, and neuropathy) or a history of stroke or previous neurological disorder within 12 months with residual symptoms. Participants with a history of migraine or chronic headaches or nerve root compression that have been stable on treatment for the last 4 weeks are not excluded.
19. Any autoimmune disease/condition (iatrogenic or congenital) listed in [Table 9-3](#) or being treated with a biologic therapy.

NOTE: The Skin and Metabolic Disorders listed in [Table 9-3](#) are eligible at the discretion of the investigator.

20. Any other significant disease, disorder or finding that, in the opinion of the investigator, may significantly increase the risk to the volunteer because of participation in the study, affect the ability of the volunteer to participate in the study, or impair interpretation of the study data.
21. Participant requires the use of continuous oxygen therapy or any oxygen therapy while awake or is anticipated to require daytime oxygen therapy during the course of the study.

NOTE: Nocturnal oxygen use only is acceptable for study inclusion.

4.3 Other Considerations

Participants meeting any of the following criteria may have planned study vaccination deferred for a later date, but these criteria are not exclusionary for study enrolment.

- Respiratory symptoms in the past 3 days (i.e., cough, sore throat, difficulty breathing). Participant may be vaccinated once all symptoms have been resolved for > 3 days. Out-of-window study vaccination is allowed for this reason (**see NOTE**).
- Temperature of > 38°C within 24 hours of planned study vaccination (site measured or participant measured). Participant may be vaccinated once the fever has resolved and there has not been any temperature measured as being > 38°C for > 3 days. Out-of-window study vaccination is allowed for this reason (**see NOTE**).

NOTE: PCR testing for SARS-CoV-2 is likely to be indicated for either of the above reasons or if COVID-19 is suspected based on other symptoms, potential exposure to SARS-CoV-2 infection through either close contacts or based on local epidemiology. If a participant has a positive PCR for SARS-CoV-2 prior to enrolment that participant will not be eligible and will be considered a screen failure.

- Participants having any symptoms or signs of possible COVID-19 infection ([Table 2-2](#)) that may also be due to post-vaccination reactogenicity within 7 days of either study vaccine dose will NOT be required to be tested for SARS-CoV-2 PCR.
- Any participant with a new positive PCR-confirmed SARS-CoV-2 infection occurring from Screening and prior to second study vaccination will not be removed from the study but must meet health requirements before receiving the second study vaccination.
- Any participant who has a positive PCR for SARS-CoV-2 between the first and second study vaccination should also have PCR testing for SARS-CoV-2 on the day of the subsequent study vaccination, but the results of the PCR test are not needed before study vaccination can be given.
- Any participant with a new positive PCR-confirmed SARS-CoV-2 infection occurring from Screening and prior to the end of immunogenicity assessments will be removed from applicable immunogenicity analyses as defined in the SAP.

- Any acute illness (cardiovascular, endocrine, gastrointestinal, hepatic, renal, neurological, respiratory, or other medical disorders) that is actively causing symptoms that could, in the opinion of the investigator, impact the assessment of reactogenicity or other study assessments may have planned study vaccination deferred for a later date, but these criteria are not exclusionary for study enrolment. Participant may be vaccinated once symptoms have resolved or are stabilised for > 3 days. Out-of-window study vaccination is allowed for this reason.
- Any participant who is otherwise eligible with a blood pressure of $\geq 160/100$ mmHg may be retested onsite several times over a 3-hour interval to achieve a lower blood pressure. If the blood pressure remains $\geq 160/100$ mmHg, study vaccination should be deferred for a later date if the baseline blood pressure is found to be $< 160/100$ mmHg.

4.4 Withdrawal of Participants from the Study

4.4.1 Reasons for Withdrawal

Participants can withdraw consent and discontinue from the study at any time, for any reason. Participants may refuse further procedures (including study vaccination) but are encouraged to remain in the study for safety follow-up. In such cases where only safety is being conducted, participant contact could be managed via telemedicine contact (e.g., telephone, web chat, video, FaceTime).

The investigator will **withhold** further study vaccination from a participant in the study if the participant:

1. Is noncompliant with the protocol.
2. Experiences an SAE or intolerable AE(s) for which study vaccination is not advised by the investigator.
3. Becomes pregnant (discontinuation of further study vaccination required).

The investigator can also withdraw a participant upon the request of the sponsor or if the sponsor terminates the study.

4.4.2 Handling of Withdrawals

Participants are free to withdraw from the study at any time upon request. Participant participation in the study may be stopped at any time at the discretion of the investigator or at the request of the sponsor.

When a participant withdraws from the study, the reason(s) for withdrawal shall be recorded by the investigator on the relevant page of the electronic case report form (eCRF). Whenever possible, any participant who withdraws from the study prematurely will undergo all end of study (EOS) assessments. Any participant who fails to return for final assessments will be

contacted by the site in an attempt to have them comply with the protocol. The status of participants who fail to complete final assessments will be documented in the eCRF.

4.4.3 Replacements

Participants who withdraw, are withdrawn or terminated from this study, or are lost to follow-up after signing the informed consent form (ICF) but prior to first study vaccination may be replaced. Participants who receive study vaccine and subsequently withdraw, are discontinued from further study vaccination, are terminated from the study, or are lost to follow-up will not be replaced.

5. TEST ARTICLES

5.1 Study Vaccines Administered

Study vaccinations (SARS-CoV-2 rS with Matrix-M1 adjuvant or placebo) will comprise 2 IM injections (Day 0 and Day 21), ideally in alternating deltoids. For blinding purposes, all participants will be vaccinated using the same injection volume (i.e., 0.5 mL). The dose level will be 5 µg SARS-CoV-2 rS with 50 µg Matrix-M1 adjuvant (co-formulated in a single vial); placebo will be saline for injection. Study vaccinations will be administered on an outpatient basis by designated site personnel in a way to maintain the blind. Any pharmacy preparation with unblinded product will require unblinded site personnel who will not otherwise be involved in the study procedures or observation of participants.

The seasonal influenza vaccine co-administration sub-study will comprise a single IM injection (0.5 mL) of a licensed influenza vaccine on Day 0, ideally in the opposite deltoid of the study vaccine. Seasonal influenza vaccine will be administered in an open-label manner. Flucelvax Quadrivalent will be given to those 18 to 64 years of age, and an adjuvanted trivalent influenza vaccine will be given to those ≥ 65 years of age.

Whenever possible the RIGHT deltoid will be used for the influenza vaccine and the LEFT deltoid for the study vaccine.

5.2 Investigational Products

The following supplies will be used for vaccination in the study:

Investigational Product	Supplied Formulation
SARS-CoV-2 rS with Matrix-M1 adjuvant	Solution for preparation for injection, at a concentration of 5 µg antigen and 50 µg adjuvant.
Placebo	Sodium chloride injection (BP, sterile), 0.9%
Seasonal Influenza Vaccine Co-Administration Sub-Study	
Flucelvax Quadrivalent seasonal influenza vaccine	Single-dose pre-filled syringe (0.5 mL) or multi-dose vial
Adjuvanted trivalent seasonal influenza vaccine	Single-dose pre-filled syringe (0.5 mL)
Abbreviations: BP = British Pharmacopoeia; SARS-CoV-2 rS = severe acute respiratory syndrome coronavirus 2 recombinant spike protein nanoparticle vaccine.	

It is anticipated that the product will be available in a co-formulated single vial.

Further details on the study vaccine can be found in the SARS-CoV-2 rS IB.

5.2.1 Investigational Product Packaging and Storage

Novavax, Inc., will provide adequate quantities and appropriate labelling of SARS-CoV-2 rS with Matrix-M1 adjuvant and PPD will ensure distribution to the clinical sites from a designated depot. Sodium chloride injection (British Pharmacopoeia, sterile) and licensed seasonal influenza vaccine are commercially available and will be supplied by PPD. The clinical unit pharmacy will prepare the study vaccines for each participant. Detailed instructions for the preparation of study vaccine will be provided in a separate pharmacy manual.

All investigational products must be stored according to the labelled instructions in a secure cabinet or room with access restricted to necessary clinic personnel. The site will be required to keep a temperature log to establish a record of compliance with storage conditions.

5.2.2 Investigational Product Accountability

The investigator (or delegate) will maintain accurate records of receipt of all investigational product, including dates of receipt. Accurate records will be kept regarding when and how much investigational product is dispensed and used by each participant in the study. Reasons for departure from the expected dispensing regimen must also be recorded. At the completion of the study, and to satisfy regulatory requirements regarding investigational product accountability, all investigational product will be reconciled and retained or destroyed according to applicable regulations. No investigational product will be destroyed until authorised in writing by the sponsor.

5.3 Method of Assigning Participants to Study Vaccine Groups

Participants will be randomly assigned in a blinded manner using the centralised Interactive Response Technology (IRT) according to pre-generated randomisation schedules. Participants will be randomised in a 1:1 ratio via block randomisation to receive 2 IM injections of the SARS-CoV-2 rS with Matrix-M1 adjuvant or placebo. Randomisation will be stratified by site and by age ≥ 65 years. The first approximately 400 participants who qualify for the seasonal influenza vaccine co-administration sub-study (which may be at select study locations only) will be assigned prior to randomisation. These participants will be part of the solicited AE safety subset analysis. Details regarding the IRT process will be provided separately to the sites.

5.3.1 Blinding Procedures

This is an observer-blinded study. To maintain the blind, placebo vaccination via IM route will be included and unblinded site personnel will manage study vaccine logistics, preparation, and administration so as to maintain the blind from the remainder of the site personnel and participants. The unblinded site personnel will not be involved in study-related

assessments or have participant contact for data collection following study vaccine administration.

Seasonal influenza vaccine will be administered in an open-label manner.

5.3.2 Breaking the Blind

A participant's study vaccine assignment will not be broken until the end of the study for the clinical site study team unless medical treatment of the participant depends on knowing the study vaccine the participant received. In the event that the blind needs to be broken because of a medical emergency, the investigator may unblind an individual participant's study vaccine allocation.

Whenever possible, the investigator should contact the medical monitor to discuss the medical emergency and the reason for revealing the actual study vaccine received by that participant. In the event that the investigator cannot contact the medical monitor in a timely manner the blind may be broken by the investigator. The medical monitor should be contacted as soon as feasible after the unblinding. The study vaccine assignment will be unblinded through IRT. Reasons for study vaccine unblinding must be clearly explained and justified in the eCRF. The date on which the code was broken together with the identity of the person responsible must also be documented.

In the event that a safe and effective vaccine against SARS-CoV-2 is licensed and made widely available during the course of the study, a discussion with appropriate regulatory agencies will take place to discuss if the blind should be broken to offer vaccine to placebo participants.

The blind may also be broken in the event of a Suspected Unexpected Serious Adverse Reaction (SUSAR) to determine regulatory reporting.

In addition to the aforementioned situations where the blind may be broken, the data will also be unblinded to a statistical team at specified time points for planned analyses prior to study completion, as outlined in Section 7.6.

5.4 Study Vaccine Compliance

All doses of the study vaccine should be administered in the clinical unit under direct observation of clinic personnel and recorded in the eCRF. Clinic personnel will confirm that the participant has received the entire dose.

The location (right or left arm), date, and timing of all doses of study vaccine will be recorded in the participants' eCRF. If a participant is not administered study vaccine, the reason for the missed dose will be recorded.

5.5 Concomitant Medications and Prohibitive Therapy

5.5.1 Concomitant Medications

Administration of medications, therapies, or vaccines will be recorded in the eCRF. Concomitant medications will include all medications (including vaccines) taken by the participant from the time of signing the ICF through EOS (or through the early termination visit if prior to that time). Prescription and over-the-counter (OTC) drugs, as well as herbals, vitamins, and supplements, will be included.

5.5.2 Prohibitive Therapy

- No live vaccine will be allowed within 4 weeks of first study vaccination until 28 days after second study vaccination (Day 49).
- No vaccine (except for a licensed seasonal influenza vaccine and participants in the seasonal influenza co-administration sub-study) will be allowed within 2 weeks of first study vaccination until 28 days after second study vaccination (Day 49).

No influenza vaccine (except participants in the seasonal influenza co-administration sub-study) will be allowed 7 days before each vaccination.

NOTE: Participants in the seasonal influenza co-administration sub-study will be allowed to have the co-administration of a licensed seasonal influenza vaccine at the same time as first study vaccination.

- No unlicensed vaccine should be given within 45 days prior to first study vaccination until after the last study visit.
- No investigational product (drug/biologic/device) within 45 days prior to first study vaccination until after the last study visit.
- No chronic administration (defined as more than 14 continuous days) of any immunosuppressant medication within 3 months of first study vaccination until the last study visit (except topical steroids or short-term oral steroids with course lasting ≤ 14 days). The use of topical, inhaled, and nasal glucocorticoids will be permitted if other chronic disease conditions are not exclusionary.
- No continuous use of anticoagulants, such as coumarins and related anticoagulants (i.e., warfarin) or novel oral anticoagulants/anti-platelet agents. Use of ≤ 325 mg of aspirin per day as prophylaxis is permitted.

6. STUDY PROCEDURES

Written informed consent will be obtained after explanation of the aims, benefits and all safety concerns of the trial as detailed in the information sheet BEFORE any trial specific procedures are performed. They should take as much time as they need to consider joining the study. Signed consent will be kept by the investigator and documented in medical notes and a copy given to the participant, as described in Section 9.3.2.3 (Appendix 2).

Due to the ongoing pandemic, recent national regulatory and local Ethics Committee and public health guidance will be applied at the site locations regarding alternations in the ability of study participants to attend an investigational site for protocol-specified visits, with the site's investigator being allowed to conduct safety assessments (e.g., telephone contact, alternative location for assessment, including local laboratories or imaging centres) when necessary and feasible, as long as such visits are sufficient to assure the safety of study participants. Serum samples may be drawn using local phlebotomy services, home health, or other modalities if site visits cannot occur. Study vaccination visits must have adequate oversight for issues associated with immediate severe reactions.

6.1 Study Visit Procedures

6.1.1 Days -30 to 0 – Screening

The following procedures will be performed within 30 days of first study vaccination. The Screening visit and Day 0 visit may be combined, if feasible, at any given study site.

- Written informed consent will be obtained in conformance with Section 9.3.2.3 of this protocol.
- Review of medical history, including prior and concomitant medical conditions, recent vaccinations (≤ 90 days), and significant surgical procedures.
- Inclusion and exclusion criteria review consistent with Section 4. Specific exclusions to study vaccination will be assessed before any vaccination. Waivers to enrolling participants with exclusions will not be given.
- Demographics, including date of birth (day, month, and year), sex, race, ethnicity, weight, and height.
- Prior and concomitant medications, including recent and current medications at the time of screening to be reviewed to ensure eligibility criteria are fulfilled. Concomitant medications include all medications (including vaccines) taken by the participant.
- Vital sign measurements, including respiratory rate, blood pressure, pulse rate, pulse oximetry, and oral temperature (or via forehead/ear reader).
- Urine pregnancy test for women of childbearing potential only. A positive urine pregnancy test at Screening will result in screen failure.

- Physical examination to include height and weight; head, eyes, ears, nose, and throat (HEENT), neck, thyroid, lungs, heart, cardiovascular, abdomen, lymph nodes of the upper extremities and neck; and musculoskeletal system/extremities to allow for study vaccination.
- Nose/throat samples will be collected to test for SARS-CoV-2 (PCR) only if the participant has any COVID-19 symptoms or significant exposure history. If a participant has a positive PCR for SARS-CoV-2 prior to enrolment that participant will not be eligible and will be considered a screen failure.
- Assessment of SAEs, starting from the time of informed consent.

6.1.2 Day 0 – First Study Vaccination

The Screening and Day 0 Visits may be combined whenever feasible.

All participants with confirmed eligibility will have the following procedures performed:

- Inclusion and exclusion criteria review consistent with Section 4. Specific exclusions to study vaccination will be assessed before any study vaccination.
- Prior and concomitant medications, including recent and current medications to be reviewed to ensure eligibility criteria are fulfilled. Concomitant medications include all medications (including vaccines) taken by the participant.
- Urine pregnancy test for women of childbearing potential only. A urine pregnancy test will be performed prior to each study vaccination. A positive urine pregnancy test at any time will result in the participant not receiving any further study vaccination.
- Symptom-directed (targeted) physical examination, including lymphatic assessment of injected upper extremity. Physical examination must be done prior to study vaccination.
- Blood sampling for SARS-CoV-2 prior to study vaccination (ELISA for anti-N-protein serology) in all participants.
- Blood sampling for SARS-CoV-2 prior to study vaccination (ELISA for anti-S-protein serology) in approximately 900 participants in the Anti-S Protein Serology Subset.
- Blood sampling for SARS-CoV-2 neutralisation assay prior to study vaccination in approximately 900 participants in the Neutralisation Assay Subset.
- Blood sampling for HAI prior to study vaccination for participants who received licensed seasonal influenza vaccine on Day 0 in the approximately 400 participants in the licensed seasonal influenza co-administration sub-study.
- Blood sampling for cell-mediated assessments prior to study vaccination, as measured by enzyme-linked immune absorbent spot (ELISpot) ± intracellular cytokine staining, in approximately 450 participants in the Cell-mediated Assay Subset.

- Nose/throat samples will be collected to test for SARS-CoV-2 (PCR) to determine current infection with SARS-CoV-2 and to demonstrate the methods required for nose/throat sample collection; participants will be taught how to self-sample at this time. Participants with possible COVID-19 symptoms will not be randomised but may return when symptoms have resolved per protocol. Participants found to be SARS-CoV-2 positive on Day 0 will be excluded from some analyses of the study as per the SAP.
- Randomisation.
- Pre-injection vital sign collection (respiratory rate, blood pressure, pulse rate, pulse oximetry, and oral temperature [or via forehead/ear reader]) before study vaccination to ensure participant has no evidence of fever prior to study vaccination.
- Alcohol swab cleansing of the injection sites for both study vaccine (SARS-CoV-2 rS with Matrix-M1 adjuvant or placebo) and licensed seasonal influenza vaccination (first approximately 400 eligible participants).
- Vaccination of study vaccine as an IM injection into the deltoid muscle. The first approximately 400 eligible participants will also receive an IM injection of a licensed seasonal influenza vaccine in the opposite deltoid following study vaccination.
- Monitoring for reactogenicity, participants will remain in clinic for at least 30 minutes to be monitored for any severe reactogenicity. Severe reactions will be noted as AEs on day of study vaccination.
- Post-injection vital sign collection (respiratory rate, blood pressure, pulse rate, pulse oximetry, and oral temperature [or via forehead/ear reader]) at approximately 15 to 30 minutes after study vaccination to check for any reactions to the study vaccine.
- Monitoring for COVID-19. Participants will monitor for COVID-19 symptoms. This will include provision of a Study Identification (ID) Card that provides details on study participation, study site contact information, and assessment of symptoms of suspected COVID-19 (see [Table 2-2](#)). Instructions to participants to contact the study site within 24 hours for symptoms of suspected COVID-19 will be given. A participant with suspected or confirmed COVID-19 will be asked to complete a COVID-19 symptom diary for 10 days. The Study ID Card should be presented to healthcare providers not affiliated with the study who encounter participants with symptoms of suspected COVID-19. Symptoms of reactogenicity within 7 days post-vaccination may not trigger the actions associated with COVID-19 monitoring.
- Assessment of unsolicited AEs, MAAEs (all and related to study vaccination), SAEs, and AESIs.

6.1.3 Day 21 – Second Study Vaccination (+ 7 days)

All participants will have the following procedures performed:

- Prior and concomitant medications. Concomitant medications include all medications (including vaccines) taken by the participant.
- Urine pregnancy test for women of childbearing potential only. A urine pregnancy test will be performed prior to each study vaccination. A positive urine pregnancy test at any time will result in the participant not receiving any further study vaccination.
- Symptom-directed (targeted) physical examination, including lymphatic assessment of injected upper extremity. Physical examination must be done prior to study vaccination.
- Blood sampling for HAI for participants who received licensed seasonal influenza vaccine on Day 0 in the approximately 400 participants in the licensed seasonal influenza co-administration sub-study.
- Nose/throat samples will be collected to test for SARS-CoV-2 (PCR) only if the participant has any COVID-19 symptoms or significant exposure history between Days 0 and 21. Results of that test are not required for study vaccination, but participants who are symptomatic may have second study vaccination delayed per protocol. Participants found to be SARS-CoV-2 positive on Day 21 will be excluded from the immunogenicity analyses of the study as per the SAP.
- Pre-injection vital sign collection (respiratory rate, blood pressure, pulse rate, pulse oximetry, and oral temperature [or via forehead/ear reader]) before study vaccination to ensure participant has no evidence of fever prior to study vaccination.
- Alcohol swab cleansing of the injection site for study vaccine (SARS-CoV-2 rS with Matrix-M1 adjuvant or placebo).
- Vaccination of study vaccine as an IM injection into the opposite deltoid muscle of the Day 0 study vaccine.
- Monitoring for reactogenicity, participants will remain in clinic for at least 30 minutes to be monitored for any severe reactogenicity. Severe reactions will be noted as AEs on day of study vaccination.
- Post-injection vital sign collection (respiratory rate, blood pressure, pulse rate, pulse oximetry, and oral temperature [or via forehead/ear reader]) at approximately 15 to 30 minutes after study vaccination to check for any reactions to the study vaccine.
- Monitoring for COVID-19. Participants will monitor for COVID-19 symptoms. This will include provision of a Study ID Card that provides details on study participation, study site contact information, and assessment of symptoms of suspected COVID-19 (see [Table 2-2](#)). Instructions to participants to contact the study site within 24 hours for symptoms of suspected COVID-19 will be given. A participant with suspected or confirmed COVID-19 will be asked to complete a COVID-19 symptom diary for 10 days. The Study ID Card should be presented to healthcare providers not affiliated with the study who encounter participants with symptoms of suspected COVID-19.

Symptoms of reactogenicity within 7 days post-vaccination may not trigger the actions associated with COVID-19 monitoring.

- Assessment of unsolicited AEs, MAAEs (all and related to study vaccination), SAEs, and AESIs.

6.1.4 Day 35 – Follow-up Visit (+ 7 days)

All participants will have the following procedures performed:

- Prior and concomitant medications. Concomitant medications include all medications (including vaccines) taken by the participant.
- Symptom-directed (targeted) physical examination, including lymphatic assessment of injected upper extremity.
- Blood sampling for SARS-CoV-2 (ELISA for anti-N-protein serology) in all participants.
- Blood sampling for SARS-CoV-2 (ELISA for anti-S-protein serology) in approximately 900 participants in the Anti-S Protein Serology Subset.
- Blood sampling for SARS-CoV-2 neutralisation assay in approximately 900 participants in the Neutralisation Assay Subset.
- Blood sampling for cell-mediated assessments, as measured by ELISpot ± intracellular cytokine staining, in approximately 450 participants in the Cell-mediated Assay Subset.
- Monitoring for COVID-19. Participants will monitor for COVID-19 symptoms. This will include provision of a Study ID Card that provides details on study participation, study site contact information, and assessment of symptoms of suspected COVID-19 (see [Table 2-2](#)). Instructions to participants to contact the study site within 24 hours for symptoms of suspected COVID-19 will be given. A participant with suspected or confirmed COVID-19 will be asked to complete a COVID-19 symptom diary for 10 days. The Study ID Card should be presented to healthcare providers not affiliated with the study who encounter participants with symptoms of suspected COVID-19.
- Assessment of unsolicited AEs, MAAEs (all and related to study vaccination), SAEs, and AESIs.

6.1.5 COVID-19 Surveillance Visits (Unscheduled)

6.1.5.1 Initial COVID-19 Surveillance Visit

All participants will have the following procedures performed:

- Review of medical history, including prior and concomitant medical conditions, recent vaccinations (≤ 90 days), and significant surgical procedures.
- Prior and concomitant medications. Concomitant medications include all medications (including vaccines) taken by the participant.
- Vital sign measurements, including respiratory rate, blood pressure, pulse rate, pulse oximetry, and oral temperature (or via forehead/ear reader).
- Symptom-directed (targeted) physical examination, including a respiratory assessment.
- COVID-19 Symptom Diary. A participant with suspected or confirmed COVID-19 will be asked to complete the COVID-19 symptom diary. Participants should start the diary on their first day of symptoms and complete this diary daily for a minimum of 10 days even if their symptoms have resolved and regardless of any SARS-CoV-2 PCR results. They should continue the diary beyond 10 days if they have any ongoing symptoms related to the episode and should continue to do so until all symptoms have resolved.
- Assessment of MAAEs (related to study vaccination), SAEs, and AESIs.

6.1.5.2 Follow-up COVID-19 Surveillance Visit

A Follow-Up COVID-19 Surveillance Visit will occur approximately 7 (+ 3) days after the Initial COVID-19 Surveillance Visit to ascertain worsening/progression of COVID-19 symptoms.

All participants will have the following procedures performed:

- Review of medical history, including prior and concomitant medical conditions, recent vaccinations (≤ 90 days), and significant surgical procedures.
- Prior and concomitant medications. Concomitant medications include all medications (including vaccines) taken by the participant.
- Vital sign measurements, including respiratory rate, blood pressure, pulse rate, pulse oximetry, and oral temperature (or via forehead/ear reader).
- Symptom-directed (targeted) physical examination, including a respiratory assessment.
- COVID-19 Symptom Diary. A participant with suspected or confirmed COVID-19 will be asked to complete the COVID-19 symptom diary. Participants should start the diary on their first day of symptoms and complete this diary daily for a minimum of

10 days even if their symptoms have resolved and regardless of any SARS-CoV-2 PCR results. They should continue the diary beyond 10 days if they have any ongoing symptoms related to the episode and should continue to do so until all symptoms have resolved.

- Assessment of MAAEs (related to study vaccination), SAEs, and AESIs.

6.1.6 3 Months (\pm 15 days) After Second Study Vaccination

All participants will have the following procedures performed:

- Prior and concomitant medications. Concomitant medications include all medications (including vaccines) taken by the participant.
- Blood sampling for SARS-CoV-2 (ELISA for anti-N-protein serology) in all participants.
- Monitoring for COVID-19. Participants will monitor for COVID-19 symptoms. This will include provision of a Study ID Card that provides details on study participation, study site contact information, and assessment of symptoms of suspected COVID-19 (see [Table 2-2](#)). Instructions to participants to contact the study site within 24 hours for symptoms of suspected COVID-19 will be given. A participant with suspected or confirmed COVID-19 will be asked to complete a COVID-19 symptom diary for 10 days. The Study ID Card should be presented to healthcare providers not affiliated with the study who encounter participants with symptoms of suspected COVID-19.
- Assessment of MAAEs (related to study vaccination), SAEs, and AESIs.

6.1.7 6 Months (\pm 15 days) After Second Study Vaccination

All participants will have the following procedures performed:

- Prior and concomitant medications. Concomitant medications include all medications (including vaccines) taken by the participant.
- Blood sampling for SARS-CoV-2 (ELISA for anti-N-protein serology) in all participants.
- Monitoring for COVID-19. Participants will monitor for COVID-19 symptoms. This will include provision of a Study ID Card that provides details on study participation, study site contact information, and assessment of symptoms of suspected COVID-19 (see [Table 2-2](#)). Instructions to participants to contact the study site within 24 hours for symptoms of suspected COVID-19 will be given. A participant with suspected or confirmed COVID-19 will be asked to complete a COVID-19 symptom diary for 10 days. The Study ID Card should be presented to healthcare providers not affiliated with the study who encounter participants with symptoms of suspected COVID-19.
- Assessment of MAAEs (related to study vaccination), SAEs, and AESIs.

6.1.8 12 Months (\pm 15 days) After Second Study Vaccination

All participants will have the following procedures performed:

- Prior and concomitant medications. Concomitant medications include all medications (including vaccines) taken by the participant.
- Blood sampling for SARS-CoV-2 (ELISA for anti-N-protein serology) in all participants.
- Monitoring for COVID-19. Participants will monitor for COVID-19 symptoms. This will include provision of a Study ID Card that provides details on study participation, study site contact information, and assessment of symptoms of suspected COVID-19 (see [Table 2-2](#)). Instructions to participants to contact the study site within 24 hours for symptoms of suspected COVID-19 will be given. A participant with suspected or confirmed COVID-19 will be asked to complete a COVID-19 symptom diary for 10 days. The Study ID Card should be presented to healthcare providers not affiliated with the study who encounter participants with symptoms of suspected COVID-19.
- Assessment of MAAEs (related to study vaccination), SAEs, and AESIs.

6.2 Efficacy assessments

6.2.1 Nose/Throat Samples for Virus Detection

Nose/throat samples for virus detection will be taken at the study visits described in the schedule of events (SOE) ([Table 3-1](#)).

- Nose/throat samples will be not be taken at Screening unless participants have symptoms or significant exposure to SARS-CoV-2. If a participant has a positive PCR for SARS-CoV-2 prior to enrolment that participant will not be eligible and will be considered a screen failure.
- Nose/throat samples will be taken on Day 0 to determine current infection with SARS-CoV-2 and to demonstrate the methods required for nose/throat sample collection. Participants will be taught how to self-sample at this time. Participants with possible COVID-19 symptoms will not be randomised but may return when symptoms have resolved per protocol. Participants found to be SARS-CoV-2 positive on Day 0 will be excluded from the immunogenicity analyses of the study as per the SAP.
- Nose/throat samples will be not be routinely taken on Day 21. Participants with possible COVID-19 symptoms that develop between Day 0 and Day 21 may have a SARS-CoV-2 PCR test performed prior to second study vaccination on Day 21. Results of that test are not required for vaccination, but participants who are symptomatic may be have the second study vaccination delayed per protocol. Participants found to be SARS-CoV-2 positive on Day 21 will be excluded from the immunogenicity analyses of the study as per the SAP.

6.2.2 Virologic Confirmation of SARS-CoV-2

Nose/throat sampling will be performed to virologically confirm (by PCR to SARS-CoV-2) the presence of SARS-CoV-2 beginning on Day 0 until the EOS, yet only those SARS-CoV-2 cases detected 7 days after second study vaccination will be utilised in study efficacy endpoints.

If a participant experiences any symptom in [Table 2-2](#), this will trigger:

- Nose/throat self-sampling once daily for 3 consecutive days. If any test is found to be positive before 3 consecutive days of testing is performed, the full 3 consecutive tests may not be required. Participants will self-sample based on the training given on Day 0.
- Nose/throat sampling will be started approximately 24 hours after the first symptom(s) from [Table 2-2](#) are reported.

The logistics and processing of these samples is being coordinated by the Department of Health and Social Care (DHSC) (UK government) as part of the national community testing programme.

6.2.3 Monitoring for Suspected COVID-19

Identification and laboratory confirmation of SARS-CoV-2 infection and symptomatic COVID-19 will be performed throughout the study.

On study enrolment, participants will be given details of a 24/7 on-call number to contact the study team. Participants will be instructed to contact the study team within 24 hours via this number if they self-assess COVID-19 symptoms in [Table 2-2](#) or are clinically concerned. Newly discovered symptoms of suspected COVID-19 will trigger a COVID-19 Surveillance Visit.

Please refer to [Table 2-2](#) for the qualifying symptoms of suspected COVID-19 disease.

Participants will receive weekly reminders (email or text messages) to immediately contact the study team if they have experienced any new symptoms or health concerns that could be related to infection with SARS-CoV-2. Newly discovered symptoms of suspected COVID-19 will trigger a COVID-19 Surveillance Visit.

A participant with suspected or confirmed COVID-19 will be asked to complete the COVID-19 symptom diary. Participants should start the diary on their first day of symptoms and complete this diary daily for a minimum of 10 days even if their symptoms have resolved and regardless of any SARS-CoV-2 PCR results. They should continue the diary beyond 10 days if they have any ongoing symptoms related to the episode and should continue to do so until all symptoms have resolved.

The occurrence of COVID-19-related hospitalisation and COVID-19-related complications (such as, but not limited to, pneumonia, neurological or vascular complications, severe pneumonia, severe neurological or vascular events, acute respiratory distress syndrome, renal complications, sepsis, septic shock, death) will be monitored throughout the study.

Every episode of a new onset of symptoms of suspected COVID-19 will trigger a COVID-19 Surveillance Visit (Initial and Follow-Up). A “new onset” episode will require at least a 7-day period of being symptom-free prior to the event to differentiate a specific episode from any prior illness.

6.2.3.1 Severity of COVID-19 Symptoms

COVID-19 symptoms will be categorised as virologically confirmed, mild, moderate, or severe as described in [Table 2-1](#).

6.2.3.2 COVID-19 Surveillance Visit (Initial and Follow-up)

A COVID-19 Surveillance Visit (Initial and Follow-Up) will be triggered by symptoms of suspected COVID-19 captured by surveillance.

When a participant is determined to have a new onset of symptoms, the participant will contact the study team immediately, begin their COVID-19 symptom diary and begin the 3 consecutive days of PCR self-testing (beginning approximately 24 hours after the start of symptoms) as above. Participants will be asked to attend an Initial COVID-19 Surveillance Visit at the study clinic or will be seen at an in-home visit by study staff depending on local conditions.

6.2.3.2.1 Initial COVID-19 Surveillance Visit

An Initial COVID-19 Surveillance Visit will be performed at the study site (or home) and will occur as soon as possible within approximately **1-3 days** of new symptom onset (however, data from specimens obtained up to 14 days will be accepted). The visit will consist of the following:

- Review and confirmation of the history of COVID-19 symptoms, including approximate date of onset of illness and solicitation of each symptom (see [Table 2-2](#)).
- Vital signs, including resting respiratory rate (on room air) and pulse oximetry, will be captured as numerical values. Lung auscultation (exam) will be performed.
- Ascertainment of any unscheduled healthcare visit by the participant (or home visit by a healthcare provider) in response to symptoms of suspected COVID-19.
- Ascertainment of new concomitant medications (especially antibiotics) or altered doses/frequencies of existing concomitant medications resulting from symptoms of suspected COVID-19.

6.2.3.2.2 Follow-Up COVID-19 Surveillance Visit

A Follow-Up COVID-19 Surveillance Visit will occur approximately 7 (+ 3) days after the Initial COVID-19 Surveillance Visit. This visit will consist of the following:

- Study staff will conduct the Follow-Up COVID-19 Surveillance Visit approximately 7 (+ 3) days after the Initial COVID-19 Surveillance Visit to ascertain worsening/ progression of COVID-19 symptoms. This follow-up visit by study staff will include all of the same procedures outlined in this section, including review of symptom history, measurement of vital signs (including pulse oximetry), and lung auscultation.

After the Follow-Up COVID-19 Surveillance Visit, participants will continue to receive telephone contacts approximately every week for ascertainment of COVID-19 symptom status until resolution of symptoms. Subsequent calls will document resolution or return to baseline of COVID-19 symptoms in order to calculate illness duration (date of symptom onset to day of symptom resolution) and will collect any additional healthcare visits, hospitalisations, and/or concomitant medications due to the suspected COVID-19.

Should a participant visit an emergency room, be admitted to the hospital or a COVID-19 ward, and PCR sampling is missed, then the local public health COVID-19 diagnostic test (or COVID-19 diagnostic test performed in the healthcare setting) will be taken as a valid result. Importantly, clinical data on symptoms, vital signs, exam findings, COVID-19 and other diagnostic testing, diagnoses, and complications occurring during the suspected COVID-19 emergency room and/or hospitalisation episode will be collected from available medical records on a study specific hospitalisation/emergency room data collection form in order to assess severity.

Participants will be notified of positive SARS-CoV-2 results as soon as locally practicable due to requirements of self-isolation and potential transmission.

Note that PCR-positive COVID-19 symptoms and events captured as efficacy endpoints will NOT be doubly recorded in the AE eCRF, unless a particular illness fulfils the definition of an SAE.

6.3 Immunogenicity Assessments

Blood will be collected from all participants for humoral immunogenicity according to the time points specified in the SOE ([Table 3-1](#)).

Immune measurements (ELISA) will be conducted on serum (IgG) for SARS-CoV-2 anti-S protein serology in approximately 900 participants in the Anti-S Protein Serology Subset and on anti-N protein serology in all participants. The immunologic test for SARS-CoV-2 serology based on a non-S protein (e.g., SARS-CoV-2 N protein) will be performed to identify cases of asymptomatic infection. Additional immunogenicity assessments specific to SARS-CoV-2 (or related variants) will include a neutralising antibody assay, which will be

performed in approximately 900 participants in a Neutralisation Assay Subset. Cell-mediated immune responses, as assessed by ELISpot ± intracellular cytokine staining, will be performed in approximately 450 participants in the Cell-mediated Assay Subset. In addition, an HAI will be performed in the approximately 400 participants in the seasonal influenza vaccine co-administration sub-study.

Details on the handling, processing, and shipping of immunogenicity samples will be provided separately in a laboratory manual.

Participants will be asked to provide consent for the use of samples for future testing or assay development specific to SARS-CoV-2 (or related variants). Aliquots of all collected samples from this study may be retained for additional testing with antigens specific to SARS-CoV-2 (or related variants) for a maximum of 25 years (starting from the date at which the last participant had the last study visit), unless local rules, regulations, or guidelines require different timeframes or different procedures, in accord with participant consent.

6.4 Safety Assessments

The timing and frequency of all safety assessments are listed in the SOE ([Table 3-1](#)).

After each study vaccination, including the licensed seasonal influenza vaccine for participants in the seasonal influenza vaccine co-administration sub-study, participants will remain under observation at the study site for at least 30 minutes for the presence of any acute reactions and solicited AEs. Solicited AEs, collected through an electronic diary (e-Diary), will be recorded at each study vaccination visit from the time of study vaccination until 7 days after study vaccination in all participants in the seasonal influenza vaccine co-administration sub-study and a subgroup of all other participants. Participants in the licensed seasonal influenza vaccine co-administration sub-study will record local reactogenicity for the study vaccine injection site only.

All participants will be assessed for unsolicited AEs from the time of first study vaccination until Day 49; SAEs will be assessed from the time the informed consent is signed until completion of the participant's last study-related procedure; all MAAEs will be reported from the time of first study vaccination until Day 35; MAAEs related to study vaccination and AESIs will be reported from the time of first study vaccination until completion of the participant's last study-related procedure. All AEs will be followed until resolution or until clinically stable.

Safety assessments will include monitoring and recording of solicited (local and systemic reactogenicity events) and unsolicited AEs; MAAEs; AESI; SAEs; vital sign measurements on day of study vaccinations; and physical examination findings. COVID-19 severity will be categorised as virologically confirmed, mild, moderate, or severe according to protocol-specified criteria ([Table 2-1](#)). Recording of solicited and unsolicited AEs may be conducted by electronic data capture (EDC)/reporting. PIMMCs and AESIs specific to potential disease

enhancement for COVID-19 will also be monitored (see Section 9.5 [Appendix 4] for details).

6.4.1 Adverse Events

AEs will be assessed during the study as described in the SOE (Table 3-1) and should be followed until they are resolved, stable, or judged by the investigator to be not clinically significant. AEs will be captured after the first dose of study vaccine administered with the exception of an AE related to study procedure or one that causes a delay in study vaccine administration (e.g., acute illness).

The investigator is responsible for ensuring that all AEs and SAEs are recorded in the eCRF and reported to the sponsor, regardless of their relationship to study vaccine or clinical significance. If there is any doubt as to whether a clinical observation is an AE, the event should be reported.

6.4.1.1 Adverse Event Definitions

The investigator is responsible for reporting all AEs that are observed or reported during the study, regardless of their relationship to study vaccination or their clinical significance.

An AE is defined as any untoward medical occurrence in a participant enrolled into this study regardless of its causal relationship to study vaccination. Participants will be instructed to contact the investigator at any time after randomisation if any symptoms develop.

6.4.1.1.1 Serious Adverse Events

An SAE is defined as any event that

- results in death
- is immediately life threatening
- requires inpatient hospitalisation or prolongation of existing hospitalisation
- results in persistent or significant disability/incapacity
- is a congenital anomaly/birth defect

Important medical events that may not result in death, be life threatening, or require hospitalisation may be considered SAEs when, based upon appropriate medical judgment, they may jeopardise the participant or may require medical or surgical intervention to prevent one of the outcomes listed in this definition. Examples of such medical events include allergic bronchospasm requiring intensive treatment in an emergency room or at home, blood dyscrasias or convulsions that do not result in inpatient hospitalisation, or the development of drug dependency or drug abuse.

6.4.1.1.2 Local and General Systemic Reactogenicity Symptoms

Solicited AEs (e.g., local and general systemic reactogenicity symptoms) will be captured in the Safety Subset of approximately 2,000 participants and in the seasonal influenza vaccine co-administration sub-study of approximately 400 participants. Participants will record all local reactogenicity symptoms for each injection of study vaccine at each location (ideally in opposite deltoids) while recording of general systemic reactogenicity symptoms may not be assigned to either injection site. Local reactogenicity symptoms should not be recorded for the influenza vaccine injection site. Solicited AEs, collected through an electronic diary (e-Diary), will be recorded from the time of study vaccination until 7 days after study vaccination.

Site-specific local (arm) and general systemic reactogenicity reactions including start and stop dates will be recorded and the investigator will apply a standard toxicology grading at the subsequent study visit (Section 9.4, Appendix 3). Should any reactogenicity event extend beyond 7 days after study vaccination and be clinically significant by toxicity grade 1 or greater, then it will be recorded as an unsolicited AE with a start date on the 8th day following study vaccination and followed to resolution.

6.4.1.1.3 Adverse Events of Special Interest

Participants will be assessed for diagnosis of an AESI at all study visits. AESIs include PIMMCs, AEs specific to COVID-19, or other potential AEs that may be determined at any time by regulatory authorities as additional information concerning COVID-19 is obtained. Given the concern for cytokine storm, an AESI of cytokine release syndrome will be included as an AE specific to COVID-19. Listings of AESI are presented in Section 9.5, Appendix 4.

6.4.1.1.4 Medically Attended Adverse Events

MAAEs are defined as AEs with medically-attended visits including hospital, emergency room, urgent care clinic, or other visits to or from medical personnel for any reason. Routine study visits (including COVID-19 Surveillance Visits) will not be considered medically attended visits. MAAEs are to be reported from the time of first study vaccination until Day 35. MAAEs related to study vaccination are to be reported from the time of first study vaccination until completion of the participant's last study-related procedure, which may include contact for safety follow-up.

6.4.1.1.5 Pregnancy

Pregnancy is not considered an AE unless there is a suspicion that an investigational vaccine may have interfered with the effectiveness of a contraceptive medication. Any pregnancy that occurs during study participation must be reported using a clinical study pregnancy form. To ensure participant safety, each pregnancy must be reported to Novavax, Inc. within 2 weeks

of learning of its occurrence. If pregnancy occurs, further study vaccination will be discontinued. The pregnancy must be followed up to determine outcome (including spontaneous miscarriage, elective termination, normal birth, or congenital abnormality) and the status of both mother and child, even if the participant was discontinued from the study. Pregnancy complications and elective terminations for medical reasons must be reported as an AE or SAE. Spontaneous miscarriages must be reported as an SAE.

Any pregnancy brought to the investigator's attention after the participant has completed the study but occurring while the participant was in the study must be promptly reported to:

Sponsor Safety Monitor: [REDACTED]

6.4.1.2 Eliciting and Documenting Adverse Events

At every study visit, participants will be asked a standard question to elicit any medically-related changes in their well-being. They will also be asked if they have been hospitalised, had any accidents, used any new medications, or changed concomitant medication regimens (both prescription and OTC medications).

In addition to participant observations, AEs will be documented from any data collected on the AE page of the eCRF or other documents that are relevant to participant safety.

6.4.1.3 Reporting Adverse Events

All AEs reported or observed during the study will be recorded on the AE page of the eCRF. Information to be collected includes study vaccine, type of event, time of onset, dosage, investigator-specified assessment of severity and relationship to study vaccine and/or study procedure, time of resolution of the event, seriousness, any required treatment or evaluations, and outcome. Any AEs resulting from concurrent illnesses, reactions to concurrent illnesses, reactions to concurrent medications, or progression of disease must also be reported. All AEs will be followed until they are resolved, stable, or judged by the investigator to be not clinically significant. The Medical Dictionary for Regulatory Activities (MedDRA) will be used to code all AEs.

Any medical condition that is present at the time that the participant is screened but does not deteriorate should not be reported as an AE. However, if it deteriorates at any time during the study, it should be recorded as an AE.

Any AE that is considered serious by the investigator or that meets SAE criteria (Section 6.4.1.1.1) must be reported to the sponsor within 24 hours after the investigator has confirmed the occurrence of the SAE. The investigator will provide a causality assessment (whether there is a reasonable possibility that the study vaccine caused the event) to the study vaccine. The sponsor will be responsible for notifying the relevant regulatory authorities of any SAE, in compliance with health authority requirements, as outlined in the relevant clinical study guidelines.

For this study, the following contact information will be used for SAE reporting:

Phone: [REDACTED]

Fax: [REDACTED]

Email: [REDACTED]

6.4.1.4 Assessment of Severity

The severity (or intensity) of an AE refers to the extent to which it affects the participant's daily activities and will be classified as mild, moderate, or severe using the following criteria:

- Mild (grade 1): These events require minimal or no treatment and do not interfere with the participant's daily activities.
- Moderate (grade 2): These events result in a low level of inconvenience or require minor therapeutic measures. Moderate events may cause some interference with normal functioning.
- Severe (grade 3): These events interrupt a participant's usual daily activity and may require systemic drug therapy or other treatment. Severe events are usually incapacitating.

If the severity of an AE changes, the most intense severity should be reported. An AE characterised as intermittent does not require documentation of the onset and duration of each episode.

6.4.1.5 Assessment of Causality

The investigator's assessment of an AE's relationship to study vaccine is part of the documentation process, but it is not a factor in determining what is or is not reported in the study. If there is any doubt as to whether a clinical observation is an AE, the event should be reported.

The investigator will assess causality (i.e., whether there is a reasonable possibility that the study vaccine caused the event) for all AEs and SAEs (solicited reactions are to be considered as being related to study vaccination). The relationship will be classified as follows:

- Not related: There is not a reasonable possibility of relationship to study vaccine. The AE does not follow a reasonable temporal sequence from administration of study vaccine or can be reasonably explained by the participant's clinical state or other factors (e.g., disease under study, concurrent diseases, and concomitant medications).
- Related: There is a reasonable possibility of relationship to study vaccine. The AE follows a reasonable temporal sequence from administration of study vaccine and

cannot be reasonably explained by the participant's clinical state or other factors (e.g., disease under study, concurrent diseases, or concomitant medications), represents a known reaction to study vaccine or other vaccines in its class, is consistent with the known pharmacological properties of the study vaccine, and/or resolves with discontinuation of the study vaccine (and/or recurs with re-challenge, if applicable).

6.4.1.6 Follow-up of Adverse Events

All AEs must be reported in detail on the appropriate page of the eCRF and followed until they are resolved, stable, or judged by the investigator to be not clinically significant.

6.4.2 Vital Sign Measurements

Vital sign measurements will include oral temperature (or via forehead/ear reader), pulse rate and diastolic and systolic blood pressure (after participant is seated for at least 5 minutes), and pulse oximetry. Temperature will be recorded and graded during general systemic reactogenicity evaluation (Section 6.4.1.1.2). The other vital sign measurements will be recorded as continuous variables prior to each study vaccination. Pulse oximetry and other vital signs will be taken on room air.

On study vaccination days, vital sign measurements will be collected once before study vaccination to ensure participant has controlled blood pressure and heart rate and no evidence of fever prior to study vaccination and once more, at approximately 15 to 30 minutes after study vaccination, to check for any reactions to the study vaccine. The investigator will only apply standard toxicology grading on the day of study vaccination, both before and after study vaccination (Section 9.4, Appendix 3). If individual vital sign measurements are considered clinically significant by the investigator, study vaccination may be withheld that day, and participants may return on a subsequent day for re-evaluation and study vaccination, ideally, within the time window specified in the SOE (Table 3-1).

6.4.3 Physical Examinations

A physical examination will be performed at screening/Day 0 (at minimum, assessment of skin, head, ears, eyes, nose, throat, neck, thyroid, lungs, heart, cardiovascular, abdomen, lymph nodes of the upper extremities and neck, and musculoskeletal system/extremities). Height and weight will be measured at screening only.

A targeted or symptom-directed physical examination will be performed at the time points specified in the SOE (Table 3-1). Special attention should be made to examine the lymph nodes of the upper extremities on vaccination days and the respiratory system at all COVID-19 Surveillance Visits.

6.4.4 Safety Monitoring

Safety oversight will be conducted by an SMC during the course of the study. The SMC is an independent group of experts that monitors participant safety and advises the sponsor. The SMC members will be separate and independent of site personnel participating in this study and should not have a scientific, financial, or other conflict of interest related to this study or the sponsor. The SMC will consist of members with appropriate expertise to contribute to the interpretation of the data from this study.

A global SMC was convened to oversee the safety of the ongoing Phase 1/2 study (Protocol 2019nCoV-101) and will oversee 1 or more additional studies across the SARS-CoV-2 rS vaccine program. A separate SMC will be convened for this study. The designated SMC will monitor the safety of participants in the study and will follow an SMC charter. The SMC will review blinded and unblinded safety and reactogenicity data. The SMC will also review sufficient clinical event data to ensure detection of evidence of enhanced disease. The SMC will convene to perform safety reviews on a scheduled basis as per the SMC charter; for immediate concerns regarding safety observations during this study; and as needed.

The SMC will operate under the rules of a sponsor-approved charter that will be approved at the organisational meeting of the SMC. At this time, each data element that the SMC needs to assess will be clearly defined. Procedures for SMC reviews/meetings will be defined in the charter. The SMC will review applicable data for safety assessments (AEs by classifications) and any clinical data that may be of significance to this review (e.g., demographics, study vaccination timing, and medications). Additional data may be requested by the SMC, and interim statistical reports may be generated as deemed necessary and appropriate for this review. The SMC may receive data in aggregate and presented by study vaccine group. The SMC may also be provided with expected and observed rates of the expected AEs in an unblinded fashion and may request the study vaccine assignment be unblinded for an individual participant if required for safety assessment.

7. STATISTICAL ANALYSIS PLANS

7.1 Sample Size Calculations

This study is designed to enrol approximately 15,000 participants, randomised 1:1 into the 2 study vaccine groups. The sample size is driven by the total number of events expected to achieve statistical significance for the primary efficacy endpoint; a target of 152 primary endpoints, the mild, moderate, or severe COVID-19 cases. The target number of events of 152 was chosen to provide 90% overall power for a 60% vaccine efficacy (VE) (Table 7-1). Two formal interim analyses of efficacy and futility will be conducted based on the accumulation of approximately 43% (66 events) and 72% (110 events) of the total anticipated primary endpoints using O'Brien-Fleming boundary conditions. Power calculations were performed by 10,000 simulated trials that were created under various assumptions of VEs and analyzed using methods described in the "efficacy analysis" section without covariates. A 90% evaluability rate for the per-protocol (PP) efficacy (PP-EFF) population (assuming 10% unevaluable due to attrition and/or baseline-seropositive participants) was used for the power calculations. All simulations were performed in SAS V9.4.

Table 7-1 Power Under Various Vaccine Efficacy Assumptions

Assumed Vaccine Efficacy	Estimated Power			
	Planned Interim Analyses		At Final Analysis	Overall (At Either Interim Analysis or Final Analysis)
	First (43%)	Second (72%)		
50%	1%	19%	29%	49%
55%	2%	34%	36%	72%
60%	7%	53%	31%	90%
65%	16%	65%	17%	98%
70%	31%	64%	5%	>99%
75%	55%	45%	1%	>99%
80%	80%	20%	0%	>99%

Abbreviations: COVID-19 = coronavirus disease 2019; PCR = polymerase chain reaction; SARS-CoV-2 = severe acute respiratory syndrome coronavirus 2

7.2 Analysis Sets

The all-randomised set will include all participants who were randomised regardless of the receipt of any study vaccine (SARS-CoV-2 rS with Matrix-M1 adjuvant or placebo). The all randomised set will be used for the subject disposition summaries.

The intent-to-treat (ITT) analysis set will include all participants who are randomised and receive at least 1 dose study vaccine (SARS-CoV-2 rS with Matrix-M1 adjuvant or placebo), regardless of protocol violations or missing data. The ITT analysis set will be used as a supportive analysis population for the immunogenicity and efficacy analyses and will be analysed according to the study vaccine group as randomised.

The safety analysis set will include all participants who receive at least 1 dose of study vaccine (SARS-CoV-2 rS with Matrix-M1 adjuvant or placebo). Participants in the safety analysis set will be analysed according to the study vaccine actually received.

The PP-EFF will include baseline seronegative participants who receive both doses of study vaccine (SARS-CoV-2 rS with Matrix-M1 adjuvant or placebo) and have no major protocol deviations that occur before the first COVID-19 episode affecting the primary efficacy outcome as assessed by the sponsor prior to unblinding. All analyses of the PP-EFF population will also exclude any illness episodes with positive SARS-CoV-2 by any validated PCR or antibody test occurring before 7 days after second study vaccination (e.g., Day 28).

The per-protocol immunogenicity (PP-IMM) analysis set for each post-randomisation visit will include participants who receive scheduled dose(s) of study vaccine (SARS-CoV-2 rS with Matrix-M1 adjuvant or placebo), have at least a baseline and the serum sample result for the visit available after study vaccination, and have no major protocol violations that are considered clinically likely to impact the immunogenicity response at the corresponding study visit as assessed by the sponsor prior to unblinding. For each visit, the SARS-CoV-2 unexposed population will also exclude any illness episodes with positive SARS-CoV-2 by any validated PCR or antibody test prior to each visit. Prior exposed participants will be determined using baseline SARS-CoV-2 immunity defined as positive SARS-CoV-2 by PCR or serum IgG antibody at baseline, or positive SARS-CoV-2 by qualitative PCR through Day 35, according to the specified analysis. Analysis will be performed to assess if immune responses differ between exposed and unexposed individuals (i.e., whether prior exposure alters dosing regimen considerations in a pandemic response).

The review and determination for exclusion from the PP populations will be carried out in a blinded fashion by a study clinician prior to unblinding for each interim analysis based on all available information from the locked database. Both PP populations will be analysed according to the study vaccine group as randomised.

7.3 Statistical Analysis

Details of all statistical analyses will be described in the SAP.

All data collected will be presented in data listings. Data from participants excluded from an analysis set will be presented in the data listings but not included in the calculation of summary statistics for that analysis set.

For categorical variables, frequencies and percentages will be presented. Continuous variables will be summarised using descriptive statistics (number of participants, mean, median, minimum, and maximum).

Baseline demographic and background variables will be summarised by study vaccine group. The number of participants who enrol in the study and the number and percentage of participants who complete the study will be presented. Frequency and percentage of participants who withdraw or discontinue from the study, and the reason for withdrawal or discontinuation, will also be summarised.

7.3.1 Efficacy Analyses

The primary endpoint will be analysed on the PP-EFF Analysis Set and supported by analysis of the ITT Analysis Set. Conclusions concerning declaration of attainment of the primary endpoint at the completion of the study will only be based on the PP-EFF population.

VE is defined as $VE (\%) = (1 - RR) \times 100$, where RR = relative risk of incidence rates between the 2 study vaccine groups (SARS-CoV-2 rS with Matrix-M1 adjuvant or placebo). The final analysis for the primary objective in the PP-EFF population will be carried out at the overall one-sided Type I error rate of 0.025 for the 3 planned analyses. The nominal alpha to be spent for the final analysis will be recalculated using the Lan-DeMets alpha spending function based on the actual numbers of events used for the interim analyses and the numbers of endpoints to be used for the final analysis. The estimated RR and its CI will be derived using Poisson regression with robust error variance [Zou 2004]. The explanatory variables in the model will include study vaccine group. The dependent variable will be the incidence rate of the endpoint of interest. The robust error variances will be estimated using the repeated statement and the participant identifier. The Poisson distribution will be used with a logarithm link function. The site (depending on the distribution of endpoints) and the age strata will be included in the model as covariates. To assess incidence rates rather than absolute counts of cases, accounting for differences in follow-up times starting with 7 days after the second vaccination among participants, an offset will be utilized in the Poisson regression. In case the total number of events to be analysed may be too low for an asymptotic method proposed (i.e., ≤ 5 events in either treatment group), an alternative method based on the single sample exact binomial distribution may be used for the analysis. This method is based on the proportion of the events in the SARS-CoV-2 rS with Matrix-M1 adjuvant group among the total number of events observed in both treatment groups after

adjusting for the differential number of subjects (or inclusive of differential lengths of follow-up) between the 2 treatment groups.

Hypothesis testing of the primary efficacy endpoint will be carried out against $H_0: VE \leq 30\%$. Rejection of the null hypothesis, $H_0: VE \leq 30\%$ demonstrates a statistically significant vaccine effect (i.e., alpha-adjusted lower bound confidence interval [LBCI] $> 30\%$) will be considered meeting the prespecified study success criterion. The study will also continue for the intended duration to measure efficacy, immunogenicity, and safety endpoints, regardless of primary endpoint success at the interim analyses or the final efficacy analysis. The final formal analysis of the primary efficacy endpoint will be triggered when approximately 152 PP-EFF participants with symptomatic mild, moderate, or severe COVID-19 endpoints have accrued. Also, in order to be able to respond to the unexpected and rapidly evolving COVID-19 pandemic situation globally, other factors such as requests by government or public health agencies may also be factored into the decision-making to unblind the study for the final analysis, but this always occurs in consultation with lead regulatory agencies.

The secondary and exploratory efficacy endpoints will be analysed using the same method as the primary efficacy analysis described above. Analysis of secondary and exploratory efficacy endpoints will be performed without adjustment for multiple comparisons (i.e., two-sided alpha of 0.05). The final interpretation of the overall vaccine efficacy will be based on the totality of statistical evidence, including immunogenicity results and the clinical importance in discussions with the regulatory agencies and scientific communities. The EOS analysis will be performed when the last participant completes the last visit (12 months after the last study vaccination) or discontinues earlier.

7.3.2 Immunogenicity Analysis and Correlates of Risk

The primary and secondary immunogenicity analyses will be performed using the PP-IMM and ITT analysis populations.

For the serum antibody levels measured by microneutralization and HAI assays, the geometric mean at each study visit, the geometric mean fold rises (GMFRs) comparing to Day 0 (baseline) at each follow-up study visit, along with 95% CI will be summarised by study vaccine group. The 95% CI will be calculated based on the t distribution of the log-transformed values for geometric means or GMFRs, then back transformed to the original scale for presentation. The seroconversion rate (SCR), proportion of participants with ≥ 4 fold rises if naïve at baseline, along with 95% CIs based on the Clopper-Pearson method will be summarised by study vaccine group at each follow-up study visit.

For the subset of participants who receives the influenza vaccine concurrently with the study vaccines, comparisons of strain-specific immune responses to influenza vaccine as measured by HAI will be performed. The treatment comparison will be made by comparing the strain-specific GMTs and the SCRs. The SCR is defined as the proportion of subjects with either a

baseline reciprocal (Day 0) titre of < 10 and a post-vaccination reciprocal titre ≥ 40 , or a baseline titre of ≥ 10 and a post-vaccination titre ≥ 4 -fold higher.

For strain-specific GMTs in each treatment group, titres reported below the lower limit of quantitation (LLOQ; i.e., below the starting dilution of assay reported as “ < 10 ”) will be set to half that limit (i.e., $10 / 2 = 5$). Strain-specific GMTs will be summarized by treatment group and visit day along with the corresponding two-sided 95% CIs, by exponentiating the corresponding log-transformed means and their 95% CIs. The ratio of GMTs between treatment groups post-vaccination and the corresponding two-sided 95% CI will be calculated on log-transformed titres using the analysis of covariance (ANCOVA) with treatment group and baseline (Day 0) measurement as the covariate.

For strain-specific SCRs, the rate in percent and the corresponding two-sided exact binomial 95% CIs will be calculated using the Clopper-Pearson method. The two-sided 95% CIs for the absolute rate difference between the 2 treatment groups will be constructed using the Newcombe method.

Similar summaries will be generated for the other immunogenicity endpoints and other assays if conducted.

Correlates of risk will be assessed where immune responses are measured in all available participants, and the results compared between participants who experience a SARS-CoV-2 event and participants who do not. The goal of this analysis is to assess correlates of risk of SARS-CoV-2 infection (and potential other secondary endpoints) in the study vaccine group by comparing study vaccine-induced immune responses associated with COVID-19.

The EOS analysis will be performed when all participants in the Neutralisation Assay Subset have completed the last study visit or discontinued earlier.

7.3.3 Safety Analyses

Solicited AEs (e.g., local and general systemic reactogenicity symptoms) will be captured in the Safety Subset of approximately 2,000 participants and in the seasonal influenza vaccine co-administration sub-study of approximately 400 participants.

Numbers and percentages (with 95% CIs based on the Clopper-Pearson method) of participants with solicited local and systemic AEs through 7 days after each study vaccination will be summarised by study vaccine group and the maximum toxicity grade over 7 days after each study vaccination. The duration of solicited local and systemic AEs after each study vaccination will also be summarised by treatment group.

Unsolicited AEs will be coded by preferred term and system organ class using the latest version of the MedDRA and summarised by study vaccine group as well as by severity and relationship to study vaccine. AEs through 49 days after first study vaccination; all MAAEs

through 35 days after first study vaccination; and MAAEs related to study vaccine; SAEs; or AESI through EOS will be listed separately and summarised by study vaccine group.

Vital sign measurements will be summarised by study vaccine group using descriptive statistics at baseline and following study vaccination.

Concomitant medications will be provided in a data listing with preferred drug name as coded using the World Health Organisation drug dictionary.

7.3.3.1 Safety: Study Vaccine-Associated Enhanced Disease

Continuous monitoring for study vaccine-associated enhanced disease will be performed through the CRO and sponsor medical monitors. These events will be monitored in real-time and after each confirmed respective case. The SMC will review this data at scheduled SMC meetings throughout the study or at an ad hoc meeting if the medical monitors would like a more immediate review of the data.

7.4 Handling of Missing Data

For calculating geometric means and GMFR, immunogenicity values reported as below the LLOQ will be replaced by $0.5 \times \text{LLOQ}$. Values that are greater than the upper level of quantitation (ULOQ) will be replaced by the ULOQ. Missing results will not be imputed.

7.5 Interim Analyses

Prior to the final analysis, 2 formal interim analyses of efficacy and futility will be conducted based on the accumulation of approximately 43% (66 events) and 72% (110 events) of the total anticipated target number of the primary endpoint (152 events). For these analyses, the data needed to perform the analysis of the primary efficacy endpoint will be cleaned. The interim analyses will be performed by an unblinded Biostatistics and Programming team, and the unblinded statistician will communicate the results of the analyses to the Sponsor in terms of fulfillment or nonfulfillment of the predefined success criterion (yes/no).

Based on the communication received from the unblinded statistician, the sponsor may choose to stop the study to unblind the accrued data or to continue the study while maintaining the blind to achieve a more robust safety and efficacy data package for the regulatory submission. Any early stopping for efficacy will be based on the PP-EFF population only. The unblinded statistician and programmer team will be isolated (by firewall) from study personnel. They will complete a review independent of the study team and sponsor. The interim analyses will follow standard group-sequential design using the Lan-DeMets alpha-spending function for O'Brien-Fleming boundary conditions. [Table 7-2](#) summarizes the timing, number of endpoints, and statistical success boundaries at the planned interim analyses and the final analysis.

Table 7-2: Interim and Final Boundaries Using O’Brien-Fleming Spending Function

Planned Information Fraction (% of total endpoints)	Planned Blinded Total Number of Endpoints	Planned One-Sided Nominal Alpha	VE Boundary for LBCI > 30%
Interim analysis at 43%	66	0.00063	~75%
Interim analysis at 72%	110	0.00804	~59%
Final analysis at 100%	152	0.02246	~51%

Abbreviations: LBCI = lower bound confidence interval; VE = vaccine efficacy.

If an unplanned additional interim analyses is be added or the timing for an planned analysis is modified, the Lan-DeMets alpha-spending function will be used to adjust the nominal alphas to maintain the pre-specified overall one-sided type I error at 0.025.

7.6 Planned Analyses Prior to Study Completion

Analysis of the data will be provided on an ongoing basis for confirming success and to review safety as the study progresses. The SAP will outline the sequential nature of these reviews.

9.2 Appendix 2: List of Abbreviations

Abbreviation	Term
ACE2	Angiotensin-converting enzyme 2
AE	Adverse event
AESI	Adverse event(s) of special interest
ANCOVA	Analysis of covariance
CFR	Code of Federal Regulations
CI	Confidence interval
COVID-19	Coronavirus disease 2019
CRO	Clinical research organization
CT	Computed tomography
DHSC	Department of Health and Social Care
EBOV GP	Ebolavirus glycoprotein
eCRF	Electronic case report form
EDC	Electronic data capture
ELISA	Enzyme-linked immunosorbent assay
ELISpot	Enzyme-linked immune absorbent spot
EOS	End of study
FDA	United States Food and Drug Administration
GCP	Good Clinical Practice
GLP	Good Laboratory Practice
GMEU	Geometric mean ELISA unit
GMFR	Geometric mean fold rise
GMT	Geometric mean titre
GP	Glycoprotein
hACE2	Human angiotensin-converting enzyme 2
HAI	Hemagglutination inhibition assay
HEENT	Head, eyes, ears, nose, and throat
HIV	Human immunodeficiency syndrome
IB	Investigator's Brochure
ICF	Informed consent form
ICH	International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use
ICU	Intensive care unit
ID	Identification

Abbreviation	Term
IgG	Immunoglobulin G
IM	Intramuscular
IRT	Interactive Response Technology
ITT	Intent-to-treat
LBCI	Lower bound confidence interval
LLOQ	Lower limit of quantification
LRTI	Lower respiratory tract infection
MAAE	Medically attended adverse event
MedDRA	Medical Dictionary for Regulatory Activities
MERS	Middle Eastern Respiratory Syndrome
MHRA	Medicines and Healthcare products Regulatory Agency
NHP	Nonhuman primate
N-protein	Nucleocapsid
NZW	New Zealand White
OTC	Over-the-counter
PCR	Polymerase chain reaction
PHEIC	Public health emergency of international concern
PIMMC	Potential immune-mediated medical conditions
PP	Per-protocol
PP-EFF	PP efficacy
PP-IMM	PP immunogenicity
RR	Relative risk
RSV F	Respiratory syncytial virus fusion (protein)
S-protein	Spike
SAE	Serious adverse event
SAP	Statistical analysis plan
SARS-CoV	Severe acute respiratory syndrome coronavirus
SARS-CoV-2	Severe acute respiratory syndrome coronavirus 2
SARS-CoV-2 rS	SARS-CoV-2 recombinant spike (S) protein nanoparticle vaccine
SCR	Seroconversion rate
Sf9	<i>Spodoptera frugiperda</i> (insect cells)
SMC	Safety Monitoring Committee
SOE	Schedule of Events
SUSAR	Suspected Unexpected Serious Adverse Reaction

Abbreviation	Term
UK	United Kingdom
ULOQ	Upper limit of quantitation
VE	Vaccine efficacy
VLP	Virus-like particle
VNA	Virus neutralisation assay
WHO	World Health Organisation
ZIKA EnvD	Zika virus envelope dimers

9.3 Appendix 3: Study Governance

9.3.1 Data Quality Assurance

This study will be conducted using the quality processes described in applicable procedural documents. The quality management approach to be implemented will be documented and will comply with current International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use (ICH) guidance on quality and risk management. All aspects of the study will be monitored for compliance with applicable government regulatory requirements, current Good Clinical Practice (GCP), the protocol, and standard operating procedures. The monitor will maintain current personal knowledge of the study through observation, review of study records and source documentation, and discussion of the conduct of the study with the investigator and personnel. eCRFs and EDC will be utilised. The EDC system is validated and compliant with US Title 21 Code of Federal Regulations (CFR) Part 11 and local regulations. Each person involved with the study will have an individual identification code and password that allows for record traceability.

Important protocol deviations, should they occur during the study, will be presented in Section 10.2 of the clinical study report.

9.3.2 Investigator Obligations

The following administrative items are meant to guide the investigator in the conduct of the study and may be subject to change based on industry and government standard operating procedures, working practice documents, or guidelines. Changes will be reported to the Research Ethics Committee (REC) but will not result in protocol amendments.

9.3.2.1 Confidentiality

All laboratory specimens, evaluation forms, reports, and other records will be identified in a manner designed to maintain participant confidentiality. All records will be kept in a secure storage area with limited access. Clinical information will not be released without the written permission of the participant, except as necessary for monitoring and auditing by the sponsor, its designee, relevant regulatory authority(ies), or the REC.

The investigator and all employees and co-workers involved with this study may not disclose or use for any purpose other than performance of the study, any data, record, or other unpublished, confidential information disclosed to those individuals for the purpose of the study. Prior written agreement from the sponsor or its designee must be obtained for the disclosure of any said confidential information to other parties.

9.3.2.2 Institutional Review

Prior to initiation of a study site, regulatory authority regulations and the ICH E6(R2) guidelines require that approval be obtained from the REC before participation of human participants in research studies. Before study onset, the protocol, informed consent, advertisements to be used for the recruitment of study participants, and any other written information regarding this study to be provided to the participant must be approved by the REC. Documentation of all REC approvals and of the REC compliance with the ICH E6(R2) guidelines will be maintained by the study site and will be available for review by the sponsor or its designee.

All REC approvals should be signed by the REC chairman or designee and must identify the REC name and address, the clinical protocol by title or protocol number or both and the date approval or a favourable opinion was granted.

9.3.2.3 Participant Consent

Written informed consent in compliance with US Title 21 CFR Part 50 and local regulatory authority requirements shall be obtained from each participant before he or she enters the study or before any unusual or nonroutine procedure that involves risk to the participant is performed. If any institution-specific modifications to study-related procedures are proposed or made by the study site, the consent should be reviewed by the sponsor or its designee or both before REC submission. Once reviewed, the investigator will submit the ICF to the REC for review and approval before the start of the study. If the ICF is revised during the course of the study, all active participating participants must sign the revised form.

Before recruitment and enrolment, each prospective participant will be given a full explanation of the study and be allowed to read the approved ICF. Once the investigator is assured that the participant understands the implications of participating in the study, the participant will be asked to give his or her consent to participate in the study by signing the ICF.

The investigator or designee will provide a copy of the ICF to the participant. The original form shall be maintained in the participant's medical records at the study site.

9.3.2.4 Study Reporting Requirements

By participating in this study, the investigator agrees to submit reports of SAEs according to the timeline and method outlined in this protocol. In addition, the investigator agrees to submit annual reports to his or her REC as appropriate.

9.3.2.5 Financial Disclosure and Obligations

The investigator is required to provide financial disclosure information to allow the sponsor to submit the complete and accurate certification or disclosure statements required under US Title 21 CFR Part 54 and local regulations. In addition, the investigator must provide to the sponsor a commitment to promptly update this information if any relevant changes occur during the course of the investigation and for 1 year following the completion of the study.

Neither the sponsor nor PPD nor the study site is financially responsible for further testing or treatment of any medical condition that may be detected during the screening process. In addition, in the absence of specific arrangements, neither the sponsor nor PPD nor the study site is financially responsible for further treatment of the disease under study.

9.3.2.6 Investigator Documentation

Prior to beginning the study, the investigator will be asked to comply with ICH E6(R2) Section 8.2, US Title 21 of the CFR, and local regulations by providing essential documents, including but not limited to, the following:

- REC approval.
- An original investigator-signed investigator agreement page of the protocol.
- Curriculum vitae for the principal investigator and each sub-investigator. Current licensure must be noted on the curriculum vitae. They will be signed and dated by the principal investigators and sub-investigators at study start-up, indicating that they are accurate and current.
- Financial disclosure information to allow the sponsor to submit complete and accurate certification or disclosure statements required under US Title 21 CFR Part 54 and local regulations. In addition, the investigators must provide to the sponsor a commitment to promptly update this information if any relevant changes occur during the course of the investigation and for 1 year after the completion of the study.
- An REC-approved ICF, samples of study site advertisements for recruitment for this study, and any other written information about this study that is to be provided to the participant.
- Laboratory certifications and reference ranges for any local laboratories used by the study site, in accordance with US Title 42 CFR Part 493 and local regulations.

9.3.2.7 Study Conduct

The investigator agrees that the study will be conducted according to the principles of ICH E6(R2). The investigator will conduct all aspects of this study in accordance with all national, state, and local laws or regulations. The study will be conducted in compliance with

the protocol, current GCP guidelines – adopting the principles of the Declaration of Helsinki – and all applicable regulatory requirements.

Prior to study initiation, the protocol and the informed consent documents will be reviewed and approved by the sponsor and an appropriate ethics committee. Any amendment to the protocol or consent materials must also be approved by the study sponsor and REC and must be submitted, notified, or approved to the regulatory authority, as required, before they are implemented.

9.3.2.8 Case Report Forms and Source Documents

Site personnel will maintain source documentation, enter participant data into the eCRF as accurately as possible, and will rapidly respond to any reported discrepancies.

eCRFs and EDC will be utilised. The EDC system is validated and compliant with US Title 21 CFR Part 11 and local regulations. Each person involved with the study will have an individual identification code and password that allows for record traceability. Thus, the system, and any subsequent investigative reviews, can identify coordinators, investigators, and individuals who have entered or modified records, as well as the time and date of any modifications. There may be an internal quality review audit of the data and additional reviews by the clinical monitor.

Each eCRF is presented as an electronic copy, allowing data entry by site personnel, who can add and edit data, add new participants, identify and resolve discrepancies, and view records. This system provides immediate direct data transfer to the database, as well as immediate detection of discrepancies, enabling site coordinators to resolve and manage discrepancies in a timely manner.

Paper copies of the eCRFs and other database reports may be printed and signed by the investigator. This system provides site personnel, monitors, and reviewers with access to hardcopy audits, discrepancy reviews, and investigator comment information.

9.3.2.9 Adherence to Protocol

The investigator agrees to conduct the study as outlined in this protocol, in accordance with ICH E6(R2) and all applicable guidelines and regulations.

9.3.2.10 Reporting Adverse Events

By participating in this study, the investigator agrees to submit reports of SAEs according to the timeline and method outlined in this protocol. In addition, the investigator agrees to submit annual reports to his or her REC as appropriate. The investigator also agrees to provide the sponsor with an adequate report, if applicable, shortly after completion of the investigator's participation in the study.

9.3.2.11 Investigator's Final Report

Upon completion of the study, the investigator, where applicable, should inform the institution; the investigator/institution should provide the REC with a summary of the study's outcome and the sponsor and regulatory authority(ies) with any reports as required. Interim reports are expected to be provided to regulatory authorities to allow study vaccine development advancement given the pandemic situation. These reports are planned to be aggregate and at the study vaccine level unless the SMC deems additional data at the individual level (e.g., select listings of select participants) will be beneficial. In such a case, a firewall will be in place to maintain the blind for those individuals involved in the study conduct to ensure unbiased assessment continue.

9.3.2.12 Records Retention

Essential documents should be retained until at least 2 years after the last approval of a marketing application in an ICH region and until there are no pending or contemplated marketing applications in an ICH region or until at least 2 years have elapsed since the formal discontinuation of clinical development of the study vaccine or per local regulation, whichever is longer. These documents should be retained for a longer period, however, if required by applicable regulatory requirements or by an agreement with the sponsor. It is the sponsor's responsibility to inform the investigator/institution as to when these documents are no longer need to be retained.

9.3.2.13 Publications

After completion of the study, the data may be considered for reporting at a scientific meeting or for publication in a scientific journal. In these cases, the sponsor will be responsible for these activities and will work with the investigators to determine how the manuscript is written and edited, the number and order of authors, the publication to which it will be submitted, and any other related issues. The sponsor has final approval authority over all such issues.

Data are the property of the sponsor and cannot be published without their prior authorisation, but data and any publication thereof will not be unduly withheld.

9.3.3 Study Management

9.3.3.1 Monitoring

9.3.3.1.1 Monitoring of the Study

The clinical research organisation clinical monitor, as a representative of the sponsor, is obligated to follow the study closely. In doing so, the monitor will visit the investigator and study site at periodic intervals in addition to maintaining necessary telephone and email contact. The monitor will maintain current personal knowledge of the study through observation, review of study records and source documentation, and discussion of the conduct of the study with the investigator and personnel. The monitor will be blinded to study vaccine assignment. A separate unblinded study monitor will be responsible for drug accountability.

All aspects of the study will be carefully monitored by the sponsor or its designee for compliance with applicable government regulation with respect to current ICH E6(R2) guidelines and standard operating procedures.

9.3.3.1.2 Inspection of Records

The investigator and institution involved in the study will permit study-related monitoring, audits, REC review, and regulatory inspections by providing direct access to all study records. In the event of an audit, the investigator agrees to allow the sponsor, their representatives, or the regulatory authority access to all study records.

The investigator should promptly notify the sponsor of any audits scheduled by any regulatory authorities and promptly forward copies of any audit reports received to the sponsor.

9.3.3.2 Management of Protocol Amendments and Deviations

9.3.3.2.1 Modification of the Protocol

This is a Phase 3 study to evaluate the efficacy, immunogenicity, and safety of SARS-CoV-2 rS with Matrix-M1 adjuvant. This protocol is written with some flexibility to accommodate the evolving pandemic and urgency for efficacious vaccine availability. Modifications to the dose, dosing regimen, and/or clinical or laboratory procedures currently outlined below may be required to achieve the scientific goals of the study objectives and/or to ensure appropriate safety monitoring of the study participants:

- The timing of procedures for assessment of safety procedures may be modified based on newly available safety and tolerability data or evolving COVID-19 data.

- Up to an additional 25 mL of blood may be drawn for safety or immunogenicity analyses. The total blood volume withdrawn from any single participant will not exceed the maximum allowable volume during his or her participation in the entire study.
- Additional database freezes may occur as the study evolves and should the ongoing epidemic progression warrant rapid decision-making on product manufacturing. The study will continue in a blinded fashion (at the participant level) until the EOS.
- Rapid diagnostic testing for SARS-CoV-2 by point-of-care tests may be available and substituted for centralised testing if accepted by regulatory authorities as a secondary endpoint in this study and hold validity for study vaccine advancement.

It is understood that the current study may employ some or none of the alterations described above. Any changes in this research activity, except those necessary to remove an apparent immediate hazard to the participant, must be reviewed and approved by the sponsor or designee. Amendments to the protocol must be approved by the REC, and regulatory authority where applicable, before participants can be enrolled into an amended protocol.

9.3.3.2.2 Protocol Deviations

The investigator or designee must document and explain in the participant's source documentation any deviation from the approved protocol. The investigator may implement a deviation from, or a change to, the protocol to eliminate an immediate hazard to study participants without prior REC approval. As soon as possible after such an occurrence, the implemented deviation or change, the reasons for it, and any proposed protocol amendments should be submitted to the REC for review and approval, to the sponsor for agreement, and to the regulatory authorities, if required.

A protocol deviation is any change, divergence, or departure from the study design or procedures defined in the protocol. An important deviation (sometimes referred to as a major or significant deviation) is a subset of protocol deviations that leads to a participant being discontinued from the study or significantly affects the participant's rights, safety, or well-being and/or the completeness, accuracy, and reliability of the study data. An important deviation can include nonadherence to inclusion or exclusion criteria or nonadherence to regulatory authority including ICH E6(R2) guidelines.

Protocol deviations will be documented by the clinical monitor throughout the course of monitoring visits. The investigator will be notified in writing by the monitor of deviations. The REC should be notified of all protocol deviations, if appropriate, in a timely manner.

9.3.3.3 Study Termination

Although the sponsor has every intention of completing the study, they reserve the right to discontinue it at any time for clinical or administrative reasons.

The end of the study is defined as the date on which the last participant completes the last study visit (including the EOS visit and any additional long-term follow-up). Any additional long-term follow-up that is required for monitoring of the resolution of an AE or finding may be appended to the clinical study report.

9.3.3.4 Final Report

Regardless of whether the study is completed or prematurely terminated, the sponsor will ensure that clinical study reports are prepared and provided to regulatory agency(ies) as required by the applicable regulatory requirement(s). The sponsor will also ensure that clinical study reports in marketing applications meet the standards of the ICH E3: Structure and Content of Clinical Study Reports.

Where required by applicable regulatory requirements, an investigator signatory will be identified for the approval of the clinical study report. The investigator will be provided reasonable access to statistical tables, figures, and relevant reports and will have the opportunity to review complete study results.

9.4 Appendix 4: FDA Toxicity Grading Scales

Table 9-1 FDA Toxicity Grading Scale for Clinical Abnormalities (Local and General Systemic Reactogenicity)

Local Reaction to Injectable Product				
Clinical Abnormality	Mild (Grade 1)	Moderate (Grade 2)	Severe (Grade 3)	Potentially Life Threatening (Grade 4)
Pain	Does not interfere with activity	Repeated use of nonnarcotic pain reliever >24 hours or interferes with activity	Any use of narcotic pain reliever or prevents daily activity	ER visit or hospitalization
Tenderness	Mild discomfort to touch	Discomfort with movement	Significant discomfort at rest	ER visit or hospitalization
Erythema/redness ^a	2.5 – 5 cm	5.1 – 10 cm	> 10 cm	Necrosis or exfoliative dermatitis
Induration/swelling ^b	2.5 – 5 cm and does not interfere with activity	5.1 – 10 cm or interferes with activity	> 10 cm or prevents daily activity	Necrosis
Systemic (General)				
Clinical Abnormality	Mild (Grade 1)	Moderate (Grade 2)	Severe (Grade 3)	Potentially Life Threatening (Grade 4)
Fever (°C) (°F)	38.0 – 38.4 100.4 – 101.1	38.5 – 38.9 101.2 – 102.0	39.0 – 40 102.1 – 104	> 40 > 104
Nausea/vomiting	No interference with activity or 1 – 2 episodes/24 hours	Some interference with activity or >2 episodes/24 hours	Prevents daily activity, or requires outpatient IV hydration	ER visit or hospitalization for hypotensive shock
Headache	No interference with activity	Repeated use of nonnarcotic pain reliever >24 hours or some interference with activity	Significant; any use of narcotic pain reliever or prevents daily activity	ER visit or hospitalization
Fatigue/Malaise	No interference with activity	Some interference with activity	Significant; prevents daily activity	ER visit or hospitalization
Myalgia	No interference with activity	Some interference with activity	Significant; prevents daily activity	ER visit or hospitalization
Arthralgia	No interference with activity	Some interference with activity	Significant; prevents daily activity	ER visit or hospitalization

Abbreviations: DHHS = Department of Health and Human Services; ER = emergency room; FDA = United States Food and Drug Administration.

^a In addition to grading the measured local reaction at the greatest single diameter, the measurement should be recorded as a continuous variable.

^b Induration/swelling should be evaluated and graded using the functional scale as well as the actual measurement.

^c Oral temperature; no recent hot or cold beverages.

Source: [DHHS 2007](#).

Table 9-2 FDA Toxicity Grading Scale for Clinical Abnormalities (Vital Signs)

Vital Signs	Mild (Grade 1)	Moderate (Grade 2)	Severe (Grade 3)	Potentially Life Threatening (Grade 4)
Tachycardia (bpm)	101 – 115	116 – 130	> 130	ER visit or hospitalization for arrhythmia
Bradycardia (bpm) ^a	50 – 54	45 – 49	< 45	ER visit or hospitalization for arrhythmia
Hypertension (systolic) (mm Hg)	141 – 150	151 – 155	> 155	ER visit or hospitalization for malignant hypertension
Hypertension (diastolic) (mm Hg)	91 – 95	96 – 100	> 100	ER visit or hospitalization for malignant hypertension
Hypotension (systolic) (mm Hg)	85 – 89	80 – 84	< 80	ER visit or hospitalization for hypotensive shock
Respiratory Rate (breaths per minute)	17 – 20	21 – 25	> 25	Intubation

Abbreviations: DHHS = Department of Health and Human Services; ER = emergency room; FDA = United States Food and Drug Administration.

Note: Participant should be at rest for all vital sign measurements, with toxicity scored on day of study vaccination (pre- and post-dose).

^a When resting heart rate is between 60 – 100 bpm. Use clinical judgement when characterising bradycardia among some healthy participant populations (e.g., conditioned athletes).

9.5 Appendix 5: Listings of Adverse Events of Special Interest

Because it has been hypothesised that immunisations with or without adjuvant may be associated with autoimmunity, regulatory authorities have requested that Novavax instruct investigators to be especially vigilant regarding the PIMMC listed in [Table 9-3](#).

Table 9-3 Potential Immune-Mediated Medical Conditions (PIMMC)

Categories	Diagnoses (as MedDRA Preferred Terms)
Neuro-inflammatory Disorders:	Acute disseminated encephalomyelitis (including site specific variants: e.g., noninfectious encephalitis, encephalomyelitis, myelitis, myeloradiculomyelitis), cranial nerve disorders including paralyses/paresis (e.g., Bell's palsy), generalised convulsion, Guillain-Barre syndrome (including Miller Fisher syndrome and other variants), immune-mediated peripheral neuropathies and plexopathies (including chronic inflammatory demyelinating polyneuropathy, multifocal motor neuropathy and polyneuropathies associated with monoclonal gammopathy), myasthenia gravis, multiple sclerosis, narcolepsy, optic neuritis, transverse myelitis, uveitis
Musculoskeletal and Connective Tissue Disorders:	Antisynthetase syndrome, dermatomyositis, juvenile chronic arthritis (including Still's disease), mixed connective tissue disorder, polymyalgia rheumatic, polymyositis, psoriatic arthropathy, relapsing polychondritis, rheumatoid arthritis, scleroderma (including diffuse systemic form and CREST syndrome), spondyloarthritis (including ankylosing spondylitis, reactive arthritis [Reiter's Syndrome] and undifferentiated spondyloarthritis), systemic lupus erythematosus, systemic sclerosis, Sjogren's syndrome
Vasculidities:	Large vessels vasculitis (including giant cell arteritis such as Takayasu's arteritis and temporal arteritis), medium sized and/or small vessels vasculitis (including polyarteritis nodosa, Kawasaki's disease, microscopic polyangiitis, Wegener's granulomatosis, Churg–Strauss syndrome [allergic granulomatous angiitis], Buerger's disease [thromboangiitis obliterans], necrotising vasculitis and anti-neutrophil cytoplasmic antibody [ANCA] positive vasculitis [type unspecified], Henoch-Schonlein purpura, Behcet's syndrome, leukocytoclastic vasculitis)
Gastrointestinal Disorders:	Crohn's disease, celiac disease, ulcerative colitis, ulcerative proctitis
Hepatic Disorders:	Autoimmune hepatitis, autoimmune cholangitis, primary sclerosing cholangitis, primary biliary cirrhosis
Renal Disorders:	Autoimmune glomerulonephritis (including IgA nephropathy, glomerulonephritis rapidly progressive, membranous glomerulonephritis, membranoproliferative glomerulonephritis, and mesangioproliferative glomerulonephritis.
Cardiac Disorders:	Autoimmune myocarditis/cardiomyopathy
Skin Disorders:	Alopecia areata, psoriasis, vitiligo, Raynaud's phenomenon, erythema nodosum, autoimmune bullous skin diseases (including pemphigus, pemphigoid and dermatitis herpetiformis), cutaneous lupus erythematosus, morphea, lichen planus, Stevens-Johnson syndrome, Sweet's syndrome
Haematologic Disorders:	Autoimmune hemolytic anaemia, autoimmune thrombocytopenia, antiphospholipid syndrome, thrombocytopenia
Metabolic Disorders:	Autoimmune thyroiditis, Grave's or Basedow's disease, Hashimoto thyroiditis ^a , diabetes mellitus type 1, Addison's disease

Categories	Diagnoses (as MedDRA Preferred Terms)
Other Disorders:	Goodpasture syndrome, idiopathic pulmonary fibrosis, pernicious anaemia, sarcoidosis
Abbreviations: ANCA = anti-neutrophil cytoplasmic antibody; IgA = immunoglobulin A; MedDRA = Medical Dictionary for Regulatory Activities.	
^a For Hashimoto thyroiditis: new onset only.	

AESIs relevant to COVID-19 are listed in [Table 9-4](#). The list is not intended to be exhaustive, nor does it exclude the possibility that other diagnoses may be AESI. It is anticipated that additional AESI may be associated with COVID-19. Investigators should stay updated regarding such public health notifications.

Table 9-4 Adverse Events of Special Interest Relevant to COVID-19^a

Body System	Diagnoses ^a
Immunologic	Enhanced disease following immunisation, ^b cytokine release syndrome related to COVID-19 ^c , Multisystem inflammatory syndrome in children (MIS-C)
Respiratory	Acute respiratory distress syndrome (ARDS)
Cardiac	Acute cardiac injury including: <ul style="list-style-type: none"> • Microangiopathy • Heart failure and cardiogenic shock • Stress cardiomyopathy • Coronary artery disease • Arrhythmia • Myocarditis, pericarditis
Haematologic	Coagulation disorder <ul style="list-style-type: none"> • Deep vein thrombosis • Pulmonary embolus • Cerebrovascular stroke • Limb ischemia • Hemorrhagic disease • Thrombotic complications
Renal	Acute kidney injury
Gastrointestinal	Liver injury
Neurologic	Guillain-Barré Syndrome, anosmia, ageusia, meningoencephalitis
Dermatologic	Chilblain-like lesions, single organ cutaneous vasculitis, erythema multiforme

Abbreviations: AESI = adverse event of special interest; COVID-19 = coronavirus disease 2019; DAIDS = Division of AIDS; PCR = polymerase chain reaction; SARS-CoV2 = severe acute respiratory syndrome coronavirus 2.

^a To be recorded as AESIs relevant to COVID-19, these complications should be associated with a positive PCR test for SARS-CoV-2.

^b COVID-19 manifestations associated with more severe presentation and decompensation with consideration of enhanced disease potential ([SPEAC 2020](#)).

^c Cytokine release syndrome related to COVID-19 infection is a disorder characterised by nausea, headache, tachycardia, hypotension, rash, and/or shortness of breath ([DAIDS 2017](#)).
